NOAA TECHNICAL REPORT NMFS

The major responsibilities of the National Marine Fisheries Service (NMFS) are to monitor and assess the abundance and geographic distribution of fishery resources, to understand and predict fluctuations in the quantity and distribution of these resources, and to establish levels for their optimum use. NMFS is also charged with the development and implementation of policies for managing national fishing grounds, development and enforcement of domestic fisheries regulations, surveillance of foreign fishing off United States coastal waters, and the development and enforcement of international fishery agreements and policies. NMFS also assists the fishing industry through marketing service and economic analysis programs, and mortgage insurance and vessel construction subsidies. It collects, analyzes, and publishes statistics on various phases of the industry.

The NOAA Technical Report NMFS series was established in 1983 to replace two subcategories of the Technical Reports series: "Special Scientific Report—Fisheries" and "Circular." The series contains the following types of reports: Scientific investigations that document long-term continuing programs of NMFS; intensive scientific reports on studies of restricted scope; papers on applied fishery problems; technical reports of general interest intended to aid conservation and management; reports that review in considerable detail and at a high technical level certain broad areas of research; and technical papers originating in economics studies and from management investigations. Since this is a formal series, all submitted papers receive peer review and those accepted receive professional editing before publication.

Copies of NOAA Technical Reports NMFS are available free in limited numbers to governmental agencies, both Federal and State. They are also available in exchange for other scientific and technical publications in the marine sciences. Individual copies may be obtained from: U.S. Department of Commerce, National Technical Information Service, 5285 Port Royal Road, Springfield, VA 22161. Although the contents have not been copyrighted and may be reprinted entirely, reference to source is appreciated.

Acknowledgments

A project of this scope and magnitude always involves many people whose talents and skills were essential throughout its development and completion. This guide began as an idea in 1979 and has gradually evolved over the last 10 years with the assistance of numerous people. During the early stages, two major projects contracted with the University of Washington (UW) served as starting points. Kevin Howe, formerly of the UW, was asked to compile a checklist of fishes from Point Conception, California, north into the Arctic Ocean, and to set up a meristic database system. His assembled data form the basis of meristic sections on our taxonomic text pages and meristic tables. Kathryn Garrison, formerly of the UW, and Bruce Miller (UW) synthesized the available literature on the reproduction and early life history of Puget Sound fishes, and this enabled us to write many of our sections on life history.

During the several years we spent collecting data and examining material, a number of scientists donated specimens and/or unpublished data. We would like to thank the following people: Jeffrey Marliave (Vancouver Public Aquarium), David Misitano (NWAFC Mukilteo Laboratory), Albert Giorgi (NWAFC Coastal Zone and Estuarine Studies), Kevin Bailey (NWAFC Resource Assessment and Conservation Engineering), William Watson (Marine Ecological Consultants), Bruce Mundy (formerly Oregon State University), A. J. Paul (University of Alaska), Conrad Mahnken (NWAFC Manchester Field Station), Sally L. Richardson (deceased), and H. Geoffrey Moser (NMFS Southwest Fisheries Center). The complete files of the late E. H. Ahlstrom were kindly made available by H. Geoffrey Moser.

Throughout the planning, organizing, writing, and layout, many people contributed their special talents and we thank the following for their time: Theodore Pietsch, Kevin Howe, and Steven Leipertz, UW (meristic database); Kevin Howe and Steven Leipertz, UW, and Richard Bates, NWAFC, (literature database); Ralph Mintel, Richard Bates, and Michael McPhail, NWAFC (programming);

William Rugen, NWAFC (proofreading and verification); James Peacock, NWAFC (layout, typesetting); Jack McCormick and Nancy Peacock, NMFS Scientific Publications (format and editorial assistance); William Richards, formerly NMFS Scientific Editor (editorial assistance); and Michael Fahay, NMFS Northeast Fisheries Center, who has encouraged all of us along the way and who spent several days reviewing our very preliminary first draft.

We are grateful to the following, who in reviewing sections from an earlier draft made many suggestions and corrections and generously provided us with unpublished data from their personal data files: James Allen (ecology and life history), G. David Johnson (Perciformes), Wayne Laroche (Scorpaenidae, Agonidae, Carangidae), Douglas Markle (Gadiformes, Ophidiiformes), H. Geoffrey Moser (Myctophidae, Stomiiformes, Pleuronectiformes, Scorpaenidae), Bruce Mundy (meristic data), Barbara Sumida MacCall (Carangidae, Pleuronectidae, Stromateoidei), Betsy Washington (Scorpaeniformes). James Allen, Robert Lea, and Alex Peden reviewed the adult distributions and nomenclature.

The following shared unpublished figures with us: Kathryn Garrison and Jeffrey Marliave (stichaeids); Betsy Washington (cottids); William Watson (*Atherinops* and *Atherinopsis*); and Lucy Wold and Guillermo Moreno (*Sebastes mystinus*).

The following reviewed the entire draft and made many valuable suggestions, and we thank them sincerely for their time and efforts: Michael Fahay, Jeffrey Leis, Joanne Lyczkowski-Shultz, Douglas Markle, Jeffrey Marliave, Gerald McGowen, H. Geoffrey Moser, Bruce Mundy, Muneo Okiyama, William Richards, Betsy Washington, and William Watson.

Finally, we all express a special thanks to our friend and colleague Jean Dunn for his many contributions throughout the various stages of this guide. His years of experience with the early-life-history stages of North Pacific fishes and extensive knowledge of the literature were a valuable addition to this work.

ABSTRACT

This laboratory guide presents taxonomic information on eggs and larvae of fishes of the Northeast Pacific Ocean (north of California) and the eastern Bering Sea. Included are early-life-history series, illustrations, and comparative descriptions of 232 species expected to spawn here, out of a total 627 species known to occur in marine waters of this area. Meristic and general life-history data are included, as well as diagnostic characters to help identify eggs and larvae. Most of this information has been gleaned from literature, with the addition of 200 previously unpublished illustrations.

Introduction

Background

The importance of early-life-history studies to fisheries investigations and phylogenetic research has increased dramatically during the last decade. Early-life-history stages are now routinely used in fisheries studies to investigate the interannual variation in recruitment (e.g., Wooster 1983), and in studies of the phylogeny of fishes (e.g., Moser et al. 1984b). The fact that early-life-history stages of many species remain unknown in the northeastern Pacific Ocean limits their use in these disciplines, as well as in research on ecology, behavior, and the biological effects of pollution on fishes.

At the Northwest and Alaska Fisheries Center (NWAFC), progress in the identification and understanding of early-life-history stages of marine fishes has steadily increased. Our investigations beginning in 1965 were primarily aimed at determining spawning grounds and distribution of eggs and larvae for only one target species: the Pacific hake, *Merluccius productus*. Studies in the late sixties and early seventies concentrated on ascertaining abundance and horizontal distribution of the eggs and larvae of major taxa occurring off the northeast Pacific coast and in the Gulf of Alaska and Bering Sea. In addition to baseline studies on distribution and abundance, work has increasingly emphasized the use of egg and/or larval surveys (targeted on species such as walleye pollock, *Theragra chalcogramma*) to generate estimates of spawning stock biomass and to test hypotheses concerning the multitude of possible factors involved in the stock/recruitment relationship (e.g., feeding, predation, growth, and transport). These studies require the accurate identification of all early-life-history stages, from the egg stage to newly settled juveniles and adults. The ability to make such identifications is a direct result of taxonomic studies in our laboratory, especially for the family Gadidae. These studies have enabled identification of all gadid species occurring in the Northeast Pacific Ocean and have allowed additional research on development, osteology, and systematics (e.g., Matarese et al. 1981, Dunn and Vinter 1984, and Dunn and Matarese 1984).

The primary purpose of this laboratory guide is to allow expansion of the use of early-life-history studies in fisheries research by providing descriptive information necessary to insure accurate identification of eggs, larvae, and early juveniles of marine fishes in the northeastern Pacific Ocean and Bering Sea. The guide is designed to aid in species identification; thus, it includes little of the developmental information usually found in ontogenetic descriptions. We have placed emphasis on the accuracy and quality of illustrations, whether from the literature or originals drawn for this guide. In some cases, however, when specimens were not available, we reproduced substandard figures from the literature. Diagnostic characters are included, which enable identification of early-life-history stages of closely related and/or similar-looking taxa, as are comparative tables and figures which outline similarities and differences among taxa. Detailed information is included for species where considerable early-life-history data are available. For poorly known taxa, available information is given, sometimes limited to characters of adults of the species in the study area and a description of early-life-history stages of related species from other areas.

Figure 1
Study area showing geographic ranges used in species accounts.

Geographic coverage

The geographic area covered is the Pacific Ocean between approximately 38°N and 66°N and west to 180°; however, we have included only those taxa with northern limits of distribution between Oregon and the northern Bering Sea (Fig. 1). Taxa restricted to California waters or the Arctic are excluded. Because most ichthyoplankton surveys concentrate on coastal areas, usually within 200 miles (370 km) of shore, this guide emphasizes coastal, nearshore species rather than strictly oceanic species. Taxa that usually do not produce planktonic early-life-history stages are generally excluded (e.g., Embiotocidae) as are strictly freshwater and estuarine species or spawners. Sources useful in identifying early-life-history stages of freshwater and estuarine species found adjacent to our study area include Wang (1981, 1986) and Auer (1982). In general, we have based coverage on species' likelihood of spawning in the Northeast Pacific Ocean rather than on the occurrence of adults. The geographic distribution of spawning is generally more restricted than the overall range of a species. Some low-latitude oceanic species (e.g., most members of the family Scombridae) which occur off Oregon and Washington are not included because they usually spawn much further south and their eggs and larvae do not occur in our area.

Information sources

Literature In producing this guide, we first compiled meristic and life history information from the literature. This was accomplished largely through a computer-based meristic information file generated by Kevin Howe at the University of Washington, and a compendium of life history information produced under the direction of Bruce Miller, University of Washington (Garrison and Miller 1982). Information from these sources was augmented and updated as it was incorporated in this guide. The meristic database was compiled by examining specimens and original radiographs, and from the literature (original descriptions, revisions, or general sources). When possible, counts are from the left side of the body. Since Garrison and Miller (1982) is not generally available, original sources cited by them are referred to in this guide. Published early-life-history information and illustrations were used when available, supplemented when possible by data from our field collections. Among the most useful published sources were Fitch and Lavenberg (1968, 1971, 1975), Miller and Lea (1972), Hart (1973), Eschmeyer et al. (1983), Moser et al. (1984b), Ozawa (1986a), and the many papers authored or co-authored by Ahlstrom, Moser, and Richardson (see Citations). Okiyama (1988) was received too late to be fully included in this guide.

Specimens In addition to data gleaned from the literature, we have included some unpublished data and original illustrations obtained from specimens in our collections (Table 1). Specimens were from two major sources: (1) Investigations in the Kodiak Island region in the Gulf of Alaska conducted 1977-79, and (2) studies undertaken in cooperation with the U.S.S.R. beginning in 1980 to investigate the distribution and abundance of ichthyoplankton off northern California, Oregon, and Washington and in the Gulf of Alaska.

Some specimens were also derived from work in the Bering Sea during 1971-72, 1976-78, and 1979. Dunn (1986) provides a list of ichthyoplankton surveys conducted by the NWAFC from which were obtained many of the specimens examined or illustrated for this guide. Occasionally specimens were obtained from other research collections or from rearing experiments conducted primarily by Jeffrey Marliave (Vancouver Public Aquarium) and David Misitano (NWAFC).

Species list

The following list of species found in the study area was compiled from the literature. The order of higher taxa generally follows J. Nelson (1984); genera and species are listed alphabetically within families. The list is annotated with page numbers indicating where taxa are described in the guide. Page numbers are out of sequence in instances (e.g., myctophids, cottids) where taxa are grouped according to larval similarities, rather than alphabetically. Letters in place of page numbers indicate that a species is not given individual treatment for the following reasons: A = anadromous, D = direct development, F = freshwater spawner, S = spawns south of study area, U = inadequate early-life-history information available, V = viviparous. In these cases, available meristic and ecological information is given in appropriate higher-category (e.g., order, family) accounts.

Elopomorpha	31	<i>Therobrommus callorhinus</i>	U

Pigmentation Pigmentation available as taxonomic characters on larvae is limited to melanophores, since other pigment cells (e.g., xanthophores) do not retain their color in currently-used fixatives and preservatives. Melanophore patterns are very useful for identifying larval fishes. The relative size, position, and sometimes the number of melanophores in series should be noted. In some cases, pigmentation consists of a group of melanophores in a specific area; in others the pigmentation consists of an individual melanophore. Pigmentation generally changes as larvae develop. Movement of individual melanophores is rather limited, but addition or loss of melanophores is common. Usually preflexion larvae are less pigmented than later larvae, and late in the larval period, as transformation occurs, the larval pigment pattern is overgrown by the largely superficial pattern of the juvenile. Between the preflexion and transformation stages in most fish there is a definite larval pigment pattern which is relatively stable, and unique to a species in many cases. Although the position of melanophores is a species characteristic, the degree of contradiction seems to be physiologically moderated. Thus, larvae of the same species could have a different overall pigmented appearance, lighter or darker. Several species in the Northeast Pacific have heavily pigmented larvae, which are readily recognized in samples but may be confused with one another (Table 3, Fig. 5).

Morphology Larval shape can vary from stout and robust to quite slender and elongate (Table 2). Several fishes in the study area have elongate larvae which may be confused with one another (Table 4, Fig. 6). The ratio of body depth at the pectoral fin to standard length is usually sufficient to characterize overall body shape. The size and shape of the head and eye may also be important. The length of the gut, measured as the ratio of preanal to standard length, is quite useful. As with other characters, larval shape characters vary with development, so the size and stage of development should be noted when comparing shape of an unknown larva to illustrations and descriptions of known specimens.

Head spines, when present, may be more numerous and accentuated in larvae than in adults. Among Northeast Pacific fishes, larval head spines are most prevalent in cottids and scorpaenids, although they also occur in some members of groups such as perciforms and pleuronectids (Table 2).

Once the above data on an unknown specimen or group of similar specimens are assembled, actual identification becomes largely a process of eliminating species whose characters do not match the unknown specimen. Keys are not presented in this guide and generally do not work well with fish larvae, because the larvae change so much with development, and the larvae of all species in a study area are rarely known. With larvae, particularly, the first attempt should be to identify the unknown to order or family, based on meristic values, shape, and general appearance. Table 2 and the figures of larval representatives of various orders (Fig. 4) should be of assistance in this. Once an idea of the appropriate order/suborder is established, more detailed information can be obtained in the material at the beginning of each ordinal account, including general life-history characters, species represented in the study area, and meristic and early-life-history characters. Illustrations, meristics, and other information given in the individual taxon accounts in this guide should then be compared with the unknown specimens to find the most likely species. Differences between the unknown and described larvae should be noted. If an unknown specimen does not match any larval descriptions given here, check meristic tables of the most likely taxa to see if the unknown specimen fits a species whose larvae have not yet been described.

Figure 2

Examples of features used to describe early stages of fishes: A, egg; B, preflexion larva; C, late larva showing base points for measurements; D, late larva showing morphological features (B-D, after Fahay 1983).

^a *Clupea pallasii* eggs demersal.

^b Macrouridae eggs sculptured.

^c Three dorsal fins in Gadidae.

^d Macrouridae lack caudal fins.

^e Pelvic fin modified into a disc.

^f J. Nelson (1984) places scomberesocids within the Cyprinodontiformes.

^g Dorsal spines isolated from soft-rayed dorsal fin.

^h J. Nelson (1984) considers Psychrolutidae a separate family; we include it in Cottidae.

ⁱ Pelvic fin absent or modified into a disc in Cyclopteridae.

^j *Trachurus* yolk segmented.

^k Pelvic fin present only in larvae.

^l Pelvic fin absent in *Peprilus*.

^m *Lepidopsetta bilineata* only species with demersal egg.

ⁿ *Pleuronichthys* eggs have hexagonal sculpturing.

^o *Hippoglossoides elassodon* and *H. robustus* only species with wide perivitelline space.

^p Pleuronectidae eggs have no oil globule.

^q Total caudal fin rays.

^r *Mola mola* has a pseudocaudal fin (see Tyler 1980).

Figure 4
 Ranges of total vertebral counts for families in the study area.

Table 3
Distinguishing features of some commonly collected heavily pigmented larvae.*

Taxon	Distribution	Total vertebrae	Description of pigment	Other diagnostic features	Page reference
Myomeres 25-50					
<i>Rhamphocottus richardsoni</i>	SSC-Bering Sea	26-28	Small spots, densely distributed on head, gut, and 3/4 body; absent on peduncle and tail	Subterminal mouth, deep body; after flexion head spines and prickles by 9-10 mm	366
<i>Myoxocephalus</i> G	Wash.-Bering Sea	34-37	Spots concentrated dorsally on head and gut, and over anterior 1/2 body; absent over gut	Head spines develop during flexion	400
<i>Hemilepidotus</i> spp.	SSC-SE Alaska	35-39	Spots widely distributed on head, gut, and body	Head spines develop during flexion	372
<i>Scorpaenichthys marmoratus</i>	SSC-SE Alaska	35-37	Dense, uniformly distributed spots over head, gut, and 3/4 body; absent on tail	Head bumps and preopercular spines develop after flexion; preanal finfold	382
<i>Blepsias</i> spp.	Cent. Calif.-Bering Sea	37-39	Dense, large spots evenly concentrated over dorsal head, gut, and >3/4 body; absent on tail tip	Head spines and bumps develop during flexion	448
<i>Pleuronichthys</i> spp.	SSC-Bering Sea	37-41	Dense spots concentrated over head, gut, and >3/4 body; dorsal and anal finfold	Slender body with wide finfolds	616
<i>Radulinus</i> spp.	SSC-Gulf of Alaska	38-40	Widely distributed over lateral gut surface and almost 3/4 body	Preopercular spines not prominent, gut coiled	406
<i>Hemitripteris villosus</i>	Gulf of Alaska-Bering Sea	39-41	Spots evenly distributed to 3/4 body and into dorsal and anal finfold	Large size at development	452
<i>Nautichthys oculofasciatus</i>	Cent. Calif.-Bering Sea	40-41	Large, widely distributed spots to 3/4 body; dorsal and anal finfold pigment at midbody	Long, pigmented precocious pectorals; head spines, bumps, ridges develop after flexion	454
<hr style="border-top: 1px dashed black;"/>					
Myomeres >50					
<i>Hexagrammos</i> spp./ <i>Pleurogrammus monopterygius</i>	S. Calif.-Bering Sea	50-63	Widely distributed on dorsal head and gut, above and below notochord	Gut length <50% SL	348
<i>Ophiodon elongatus</i>	SSC-Gulf of Alaska	56-59	Widely distributed on dorsal head and gut, more concentrated on dorso- and ventrolateral surface; chin and isthmus	Pointed snout and large terminal mouth	346
<i>Zaprora silenus</i>	Cent. Calif.-Bering Sea	61-62	<u>Small</u> spots densely concentrated over entire body, except ventrally on gut, dorsal finfold, and posterior edge of gill cover; lightly on caudal peduncle and anal finfold	Large size at development	530
<i>Anoplopoma fimbria</i>	SSC-Bering Sea	61-66	Widely distributed over >3/4 body	>15 mm, pectoral fins long, pigmented; gut length >50% SL; anus curves ventrad	338
<i>Cololabis saira</i>	SSC-Bering Sea	62-69	Small spots densely concentrated, ventral tailtip without pigment	Long preanal finfold	236
<i>Lyconectes aleutensis</i>	N. Calif.-Bering Sea	73-75	Heavily concentrated over >3/4 body, isthmus; lighter over gut and absent on peduncle	Large size at development	520
<i>Delolepis gigantea</i>	N. Calif.-Bering Sea	81-83	Widely distributed to 3/4 body, absent over gut and isthmus	Large size at development	520

*Other heavily pigmented larvae that may be less frequently encountered include the following species:

Anarhichas orientalis (p. 524)
Naucrates ductor (p. 484)
Peprilus simillimus (p. 562)
Oxylebius pictus (p. 342)
Zaniolepis (p. 344)

Table 4
Comparison of selected diagnostic characters of some commonly collected families with similar-looking elongate larvae.

Taxon	Myomeres			Number between dorsal fin insertion and anal fin origin ^a (flexion stage)	Preanal length	Presence of adipose fin	Diagnostic pigment	Page reference
	Preanal	Postanal	Total					
Short dorsal and anal fin bases								
Clupeidae	28-32	19-23	46-57	6-8	80%	None	Gut	44
Engraulididae	24-26	19-21	43-47	0-2	67-75%	None	Isthmus, gut	48
Osmeridae ^b	—	—	54-73	9-11	80%	Yes	Single row pvm; ^c ventral gut midline	79
Long dorsal and anal fin bases								
Bathymasteridae	13-16	34-39	49-55	Overlaps	<50%	None	Urostyle or slash-like pigment along posterior hypaxial and epaxial myomeres	496
Stichaeidae	14-31	34-59	50-83	Overlaps	<50%	None	Gut, anus, pvm ^c	500
Pholididae	—	—	80-102	Overlaps	>50%	None	Gut, pvm ^c	522
Ammodytidae	40-47	23-25	65-74	Overlaps	60%	None	Double row pvm ^c	540

^a The number of myomeres between dorsal and anal fins has been used as a taxonomic character in clupeiform larvae of certain size classes. During transformation the position of the gut and median fins shifts forward relative to myomere number (for more details, see McGowan and Berry 1984).

^b Based on larvae of *Mallotus villosus* (except for total myomere count); other osmerids, as yet unidentified to species, are similar.

^c pvm = postanal ventral midline melanophores.

Format

This laboratory guide has been designed to be practical and easy to use. Only information deemed necessary for accurate and timely identification has been included. A two-page format is provided for each taxon where sufficient early-life-history information exists. The left page includes pertinent information for identification and the right page includes illustrations, usually with notations indicating important diagnostic features. The left page is divided into two columns: Information on meristic characters and life history features is presented on the left, and developmental information on the right. Blanks within the format indicate that particular information was not available (e.g., egg size, fecundity), to point out gaps in knowledge, and allow researchers to insert new information as it becomes available. The family name appears at the top of each page for quick reference. The phylogenetic sequence generally follows J. Nelson (1984) unless otherwise indicated. Species names along with their authorities appear at the upper right corner of the left page, and common names (from Robins et al. 1980, Hubbs et al. 1979, Shiino 1976, and others) are included at the upper left corner of the right page. Nomenclature generally follows Robins et al. (1980) and Steyskal (1980) unless a more recent revision is available (usually from Moser et al. 1984b). Exceptions are noted in the text.

For taxa treated at the species level, available illustrations are arranged on the right-hand page as follows: Late-stage egg is in the upper right-hand corner, and order of larvae is shown (top to bottom) as yolk sac, preflexion, flexion, postflexion, and either a transforming juvenile or special prejuvenile stage. Blank spaces indicate that stages were not available for illustration. When necessary for identification purposes, additional illustrations such as dorsal and ventral views are provided. Most illustrations were compiled from the literature; Moser et al. (1984b) provided over 100 illustrations. In a few cases, illustrations from the literature were redrawn, modified, or corrected; when this occurred, it is indicated. In addition to the published illustrations, original illustrations of 124 fish eggs and fish larvae by Beverly Vinter are included. Collection data are provided for original illustrations (Table 1).

Introductory sections are provided for each order and for taxa (usually genera or families) with difficult identification problems or for taxa that contain numerous similar species (e.g., Cottidae and *Sebastes*). Important diagnostic features are summarized, and, in some cases, tables are provided to aid in identification. In the Northeast Pacific Ocean, early-life-history stages of many species are either undescribed, incompletely described, or without adequate illustrations. For these taxa, identification material is provided at the lowest taxonomic level possible, usually family level (e.g., Osmeridae) or generic level (e.g., *Cyclothone*). Family level descriptions include a summary of available early and general life-history information, tables of meristic characters, and brief accounts of early-life-history characters from closely related taxa described from other geographic areas. For taxa where no early-life-history data are available (e.g., Cetomimoidae), life history summaries and meristic data are provided.

Meristics

Data summaries of meristic structures, except those for the caudal fin or from recently completed research, are from the NWAFC meristic database. The range (high and low value) and mode are presented for each entry. Ranges reported here generally represent the most extreme values ever recorded; in many cases, these values are not likely to be observed. These values may have been seen on specimens collected outside our study area. Thus, in using this guide more emphasis should be placed on the reported modal values. An "X" appears when data are unavailable. For fin ray counts, R = rays (soft rays) and S = spines; for gill raker counts, U = upper and L = lower. In addition to pelvic fin-ray counts, fin position is given. Position is indicated by the following descriptors: Abdominal, thoracic, jugular, absent, or modified (e.g., pelvic disc in cyclopterids). The total vertebral count given may not equal the sum of the precaudal and caudal vertebral counts in some cases, since these counts may have originated from different sources.

Data for caudal fin-ray counts have been gleaned from published material, as well as from original observations. Caudal fin-ray counts are reported in the following sequence: Upper secondary, upper principal + lower principal, lower secondary, with ranges for each when available. Total caudal fin rays or total principal caudal fin rays are reported if no other data are available. Blanks in the caudal field indicate that no data are available.

For some taxa, it was necessary to forego the standard meristic format in order to present the data or provide additional information (e.g., members of the family Gadidae have three dorsal fins and two anal fins). Departures from the standard format are either explained on the page where they occur or in introductory sections preceding species descriptions for certain taxa.

General life history

Life history data are provided as ancillary information which may aid in identification of eggs and larvae. These data were extracted from Garrison and Miller (1982) and supplemented by the general literature and original, unpublished material.

Geographic ranges are from the NWAFC meristic database and the literature. Allen and Smith (1988) provided a significant amount of new information. Range information is restricted primarily to the study area. Thus, the limits of the southern range beyond the California-Mexico border, the northern range beyond the Arctic to the north and east, and the western range beyond the Bering Sea are not specified.

The following general locations are used to approximate geographic range within the study area (abbreviations in parentheses are used hereafter in the text when necessary):

South of southern California (SSC)
Southern California, 32-34°N (S. Calif. or S. California)
Central California, 34-38°N (Cent. Calif. or Cent. California)
Northern California, 38-42°N (N. Calif. or N. California)
Oregon, 42-46°N
Washington, 46-48°30'N (Wash.)
British Columbia, 48°30'-55°N (Brit. Col.)
Southeastern Alaska, 55-59°N (SE Alaska)
Gulf of Alaska, 54-60°N
Aleutian Islands, 51-55°N (Aleutian Is.)
Bering Sea, 54-66°N
Chukchi Sea, north of 66°N
Arctic

In addition to geographic range, general ecological descriptors are incorporated in the NWAFC meristic database. The following descriptors are used.

Pelagic environment

Nearshore shelf pelagic: Extends from the shore seaward to include waters overlying an ocean bottom <200 m. Equivalent to the neritic province of Hedgpeth (1957) and other authors.

Oceanic: Waters overlying an ocean bottom >200 m. The following subdivisions based on water depth are used: Epipelagic 0-200 m; Mesopelagic 200-1000 m; Bathypelagic >1000 m.

Benthic environment

Intertidal, nearshore: Extends from high tide to low tide. Equivalent to the littoral province of many authors.

Nearshore shelf demersal: All bottom from low tide to 200 m (= epibenthic in text). Equivalent to the sublittoral zone of Hedgpeth (1957) and other authors.

Mesobenthic: Deep sea beyond the continental shelf at depths of 200-500 m. Lowest part of the shelf and upper part of continental slope (Fedorov 1973).

Bathybenthic: Deep sea along the continental slope at depths of 500-2500 m. Middle and lower sections of continental slope (Fedorov 1973).

Freshwater or anadromous: Generally the mouth and lower reaches of rivers and streams.

Other information under **Life History** includes reproductive mode (e.g., viviparous, ovoviviparous, oviparous) and indicates whether eggs and larvae are pelagic or demersal. Data on spawning are divided into four categories: Season, area, mode, and migration. Spawning often varies among geographic regions and populations, so care has been taken to provide as much specific geographic information as available. Fecundity values are given as counts of ripening eggs in individual females: Total ranges or (in a few cases) as a function of length in the form $F = aL^b$. Ages at first maturity and longevity values were extracted from the general literature. If available, age/length differences between sexes are noted.

Early life history

Egg and oil globule diameter measurements in millimeters are usually given as ranges (high and low values) with modal values as available in parentheses after the range. Precision varies among literature sources, but specimens used for original measurements were measured to the nearest 0.1 mm. Egg diameters on the illustrations are as they were given in the source. Incubation time, when available, is given in number of days to hatching for a specific temperature (°C). When describing embryonic pigment patterns, emphasis was placed on those characteristics which aid in identification. Diagnostic characters usually provide a summary of important features and comparisons with similar fish eggs.

Figure 2 provides examples of features used to describe and identify early stages of fishes. Original measurements of larvae are in millimeters and given in standard length (SL). Some measurements extracted from the literature were given as body length (BL), notochord length (NL), total length (TL), head length (HL), or percentages of these. Preanal length is usually expressed as a percentage of SL. If specific values are not available, preanal lengths are given as <50% SL, 50-75% SL, or >75% SL. Definitions for developmental stages are from Ahlstrom et al. (1976) and Kendall et al. (1984). Transformation is defined as acquisition of the adult complement of fin rays, and in some taxa this is accompanied by squamation. Sequence of fin development is usually described as the order in which fin rays accept alizarin stain, inferring ossification. For some taxa the sequence is determined by completion of the ossification of a fin element rather than the initiation of ossification (e.g., G.D. Johnson 1984); this is noted in the text. When three or more fins develop simultaneously, semicolons are used to separate the sequence of formation of one or more fins (e.g., dorsal; anal; caudal, pectoral, and pelvic). Otherwise, commas are used to separate fins developing individually in sequence (e.g., dorsal, anal, caudal, pectoral, and pelvic). Precocious fin development is usually noted. When describing pigment, those melanophores or patterns of melanophores important in identifying the taxon are stressed. Generally only melanophores are mentioned, since other pigment is not visible in formalin-preserved specimens. The general appearance, shape, and relative size of melanophores or groups of melanophores are indicated by imprecise descriptors such as spot, patch, or blotch. Diagnostic pigment characteristics are also indicated directly on the illustration page. The description of pigment is often brief and in telegraphic style and is not meant to be a substitute for more detailed discussions available in complete early-life-history descriptions. References are provided when more complete early-life-history descriptions are available. Under **Diagnostic Characters**, a brief summary of key features is provided which may help to distinguish a larval specimen from other similar larvae in either closely related taxa or from morphologically similar groups. When possible, comparative information is included in tables and is cross-referenced.

Data from the files of the late E.H. Ahlstrom are footnoted as "E.H. Ahlstrom notes." These files contain original lecture notes for classes conducted on ichthyoplankton taxonomy between 1971 and 1977, early-life-history data for most orders of fishes, and notes on teleost caudal fins. The files were made available to Kendall & Matarese by H. Geoffrey Moser (Southwest Fish. Cent., Natl. Mar. Fish. Serv., NOAA), as authors contributing to *Ontogeny and Systematics of Fishes* (Moser et al. 1984b).

Elopomorpha: Notacanthiformes Anguilliformes

The notacanthiform fishes (spiny eels) and anguilliform fishes (true eels) generally occur worldwide. The spiny eels are primarily a deep-sea group and are distinguished from the true eels by a number of characters including the absence or reduction of the caudal fin, the presence of well developed pelvic fins and fin spines, a short dorsal fin, and the presence in larvae of a thin postcaudal filament. According to Castle (1984), the Notacanthiformes consist of 3 families, 6 genera, and about 22 species; the Anguilliformes, a much larger order, include 21 families, 153 genera, and about 720 species.

The early life history of eels has been studied for many years primarily due to the presence of a distinctive leptocephalus larval phase, but many species remain inadequately known. Eggs are generally large, pelagic, possess segmented yolks, and have one or more oil globules. Although few larvae have been collected, at least 12 taxa from at least 9 families are thought to occur in the study area. Since early life histories are incomplete, this section (except for the nemichthyids) will be described by family.

Families in study area: **Notacanthidae**
Xencongridae
Nemichthyidae
Cyematidae
Synaphobranchidae
Nettastomatidae
Congridae
Serrivomeridae

ELOPOMORPHA

Key to elopomorph leptocephali in the Northeast Pacific (after Smith 1979 and Fahay 1983, in part).

Anguilliformes

Primary characters used in identifying anguilliform leptocephali are the following (Ref: E.H. Ahlstrom notes, Castle 1984, Fahay 1983, Smith 1979):

Body shape May vary from slender to deep-bodied, and the tail may be tapered or rounded.

Head characteristics Size of the head relative to the body may vary; also important are head shape (blunt, sharp, or elongate), snout shape, nasal organ (size and position), eyes (round, narrow, or telescopic), and teeth (presence/absence, fanglike if present).

Number of myomeres Usually 100-250; exceptions include *Cyema* (<100) and *Nemichthys* (>750). Preanal and predorsal counts are also useful.

Gut characteristics Gut may be a simple straight tube or more complex with loops or swellings. Relative length of gut can range from <50% SL to >90% SL, although most eels have gut lengths between 50-70% SL.

Position of vertical blood vessels Variation in the position of the last blood vessel.

Pigmentation General body pigment may be located above/below the gut, along body midline, above/below notochord internally, or along the dorsal body margin. Pigment may be in the form of fine stippling or large stellate melanophores (blotches). Head pigment also varies.

Size at transformation Maximum size before transformation can vary from <100 mm SL (most families) to ~400 mm SL (nemichthyids).

Fins Dorsal and anal fins are confluent with the caudal fin, caudal fin is usually markedly reduced with 10 or fewer rays (about 5-11 with highest numbers in synaphobranchids); pectoral fin is moderate, reduced, or lacking, and fin rays usually form late, i.e., after the leptocephalus stage. Pelvic fin is absent.

ELOPOMORPHA

Notacanthidae (234-244 myomeres)* *Notacanthus chemnitzi* and *Polyacanthonotus challengerii* both occur in the study area but their early life histories are unknown, as is the case of most notacanthids. *Leptocephalus giganteus* (identity unknown) from outside the study area is presented for comparison only. Notacanthid larvae are easily separable from larvae of true eels. Among the most notable characters are the following: Greatly elongate shape, thin postcaudal filament, and pigment which occurs in a ventral series.

Xenocoelidae (97-163 myomeres) *Thalassenchelys coheni* (142-163) may or may not belong with the xenocoelids. These larvae are quite unusual, with a short, deep body, rounded tail, and lack of pigment. They appear to be widely distributed in the northeastern Pacific from Washington to south of southern California.

Cyematidae (74-80 myomeres, most 74-78) *Cyema atrum* larvae are identified by their deep body shape, pointed head and tail, 3-4 gut loops on posterior half of gut, and low myomere count. Pigment is scattered over the lateral body surface, on the snout and lower jaw, and along the gut, especially on the loops. Other general features include gut length ~67% SL and dorsal fin origin approximately above anus. Size at transformation is 60-70 mm SL.

Synphobranchidae (subfamily Synphobranchinae) (126-151 myomeres) Synphobranchinae are represented in the Northeast Pacific by *Histiobranchus bathybius* but their larvae are unknown. Larvae in other members of the subfamily are identified by their telescopic eye, general lack of pigment, and the broad white stripe formed by an opaque central area of myomeres around the notochord. The body is moderately elongate and the head is short and pointed. The dorsal fin origin is anterior to the anus. The gut is usually relatively simple, unpigmented, and about 75% SL. Some taxa have loops in the gut. Ventral pigment is lacking, and lateral pigment is restricted to the postanal body. Some genera have a prominent pigment spot laterally, near the level of the anus. Size at transformation is 130-170 mm SL.

*Vertebral range is given for taxa in the study area. When no data are available, the range of counts for family is given (Table 5).

Figures A, D, Castle 1984; B, NWAFC original (B. Vinter); C, E, Smith 1984.

ELOPOMORPHA

Nettastomatidae (186-290 myomeres) Nettastomatids are represented in the Northeast Pacific by *Venefica* sp., but their larvae are unknown. Larvae in the family are identified by their gut characteristics (presence of two loops and gut length <50% SL) and moderately long head. The body is deep to elongate and the tail is pointed. The dorsal fin origin is posterior to the head but well anterior, at myomeres 11-12. Ventral and lateral pigment is variable. Size at transformation is also variable but occurs between 120 and 200 mm SL.

Congridae (141-219 myomeres) Congrids are represented in the area by *Xenomystax atrarius*, a member of the subfamily Muraenesocinae (larvae unknown). *Xenomystax* is closely related to *Paraxenomystax* (Smith 1979). Members of this subfamily are sometimes considered part of a separate family. Their larvae have a moderately elongate body with the gut length about 75% SL. Pigment occurs on the head, widely spaced along the throat to anus, and below the lateral midline in the form of a row of large spots. Size at transformation is probably similar to the congrid with most at 100 mm SL but some up to 200-300 mm SL.

Serrivomeridae (147-169 myomeres) *Serrivomer jespersenii* larvae are identified by a head shape that is sharp and slightly concave, pointed tail, simple gut with a length of ~75% SL, and a small nasal organ near the eye. The dorsal fin origin is located anterior to the anus. The last blood vessel occurs between myomeres 30-37. Pigment may be located variously over the lateral body surface, but ventral pigment is lacking. Other pigment appears along the dorsal and anal fin bases and in a cluster on the orbit above the eye. Size at transformation is 60 mm SL.

Eurypharyngidae (97-125 myomeres) *Eurypharynx* larvae are identified by their short, deep head and body, gut about 50-67% SL with one loop posteriorly, and pointed tail. Ventral pigment is limited to the gut loop. Size at transformation is 30-40 mm SL.

NETTASTOMATIDAE

Saurenehelys sp.

Diagnostic characters**LARVAE**

Preanal length
Length at flexion
Length at transformation
Sequence of fin development Dorsal and anal (late)

Pigment

- Small spots on top of spinal cord, at least posteriorly
- Row of spots dorsally along gut length, ventral row anterior to stomach
- Several groups (usually three) of internal spots along body subaxially—about four spots in each group^b
- Dorsal and anal fin bases

Diagnostic characters

- Distinguished from *Nemichthys* spp. by
- Body less elongate
 - Caudal structure (tail more round, not filiform)
 - Position of liver and last blood vessel, 30th and 70-88th myomere, respectively
 - Number of myomeres (181-201)

^aThe total dorsal and anal fin ray counts and the number of lateral line pores and vertebrae are often of no value; they are not comparable because caudal parts are often missing and regeneration may have occurred. Nielsen and Smith (1978) introduced artificial lengths/counts with a greater comparative value which we employ here (see their Materials and Methods section for a complete discussion), e.g., D200, A200 = number of fin rays anterior to vertebrae no. 201.

^bAccording to Smith (1979), there are three blotches of internal lateral pigment spots which become less prominent with growth.

Figures A–D, Smith 1979.

Diagnostic characters**LARVAE**

Preanal length
Length at flexion
Length at transformation ~200 mm SL
Sequence of fin development Dorsal and anal (late)

Pigment

- Three prominent spots laterally below midline in small larvae (lower on body than on *Avocettina infans*)
- Above gut along length
- Above spinal cord

Diagnostic characters

- Elongate with filiform tail
 - Number of myomeres (>300)
- Distinguished from *A. infans* by
- Position of liver (myomere 40) and last vertical blood vessel (80-100th myomere)

Nemichthys larseni larvae are not known but adults occur within the study area. See Table 5 for data on adults. Additional meristic characters from Nielsen and Smith (1978) are: D200, 173-205-222; A200, 164-200-208. See *A. infans* (p. 38, footnote a).

^aSee *Avocettina infans*.

Figures A–F, Smith 1979.

Clupeiformes

The Clupeiformes (herrings, anchovies) are generally small, coastal marine fishes that occur worldwide. Most species form schools and swim near the surface in nearshore waters, feeding on plankton. They have specialized gill rakers for straining large amounts of water. The order consists of 4 families, 78 genera, and about 317 species (McGowan and Berry 1984). Clupeids generally lay demersal eggs whereas engraulidids have pelagic eggs that are sometimes ellipsoidal in shape. Larvae are elongate and similar in appearance but may be distinguished by myomere counts and pigmentation characters.

Families in study area: **Clupeidae**
Engraulididae

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	1.3-1.7 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Segmented
Envelope	Smooth, clear, thick
Hatch size	5.6-7.5 mm SL (7 mm); yolk absorbed 9-10 mm SL
Incubation time/temp.	14-15 d/8.5°C
Pigment	

Diagnostic characters

- Wide perivitelline space

LARVAE

Preanal length	72% SL
Length at flexion	18 mm SL
Length at transformation	26-35 mm SL
Sequence of fin development	Caudal, dorsal, anal, pelvics, pectorals

Pigment

- Isthmus, thoracic region
- Gut: Dorsal, midventral (midventral melanophores on intestine usually paired, sometimes slightly offset)
- Caudal, hypural

Diagnostic characters (see Table 4)

- Distinguished from *Engraulis mordax* (p. 48) by
- More myomeres (usually >50)
 - Longer gut (consistently >70% SL)
 - Placement of dorsal fin relative to anus (6-7 myomeres between dorsal and anal fins)
 - Less isthmus pigment
 - Prominent swimbladder in *E. mordax*
 - Dorsal spots at notochord tip usually not in *E. mordax*
 - Generally more pigmented
- Distinguished from *Sardinops sagax* by
- Presence of posteroventral pigment on gut
 - Dorsal spots at notochord tip usually not in *S. sagax*

Pigment

- Isthmus
- Row of melanophores along dorsal surface of gut continuing along ventral body midline
- Ventral pigment on gut beginning about midway

Diagnostic characters (see Table 4)

- See *Clupea pallasii* (p. 44)
- Isthmus pigment present
- Dorsal and anal fin placement (0-2 myomeres between fins)
- Midventral melanophores on intestine usually staggered, not single as in osmerids, and usually not as evenly paired as in *C. pallasii*

^a Pacific Fisheries Management Council 1978^b Kendall and Clark 1982^c Blackburn 1973^d Lasker and Smith 1977^e Frey 1971^f Baxter 1967^g Clark and Phillips 1952^h Hart 1973

Figure A, Bolin 1936; B–F, Kramer and Ahlstrom 1968. Stippling in these figures is not pigment.

Salmoniformes

The salmoniform fishes (salmons, smelts, deep sea smelts, and others) are primarily freshwater spawners except for members of the Argentinoidei, the largest taxon of salmoniforms with marine eggs and larvae in our area. There is much disagreement as to the composition of the order (see Fink 1984). In our area, it consists of 4 suborders, 15 families, 90 genera, and about 320 species (J. Nelson 1984). The argentinoids are mostly deep-sea fishes. Eggs are pelagic and have distinctive pustules on the inner surface of the egg membranes; larvae have a variety of forms. Larval characters include presence/absence of eyestalks, unique development of median fins, and distinctive pigment patterns. Pigment patterns for bathylagids are discussed according to the categories described by Ahlstrom et al. (1984b)—species with large, isolated melanophores and those with a linear series of small melanophores.

A summary of meristic characters is included for Alepocephalidae and Platytroctidae. Although salmon parr are occasionally collected in plankton tows, they are not treated here. Information on their early life history is reviewed in Kendall and Behnke (1984).

Families in study area: **Argentinidae**
Bathylagidae
Opisthoproctidae
Alepocephalidae
Platytroctidae
Osmeridae
Salmonidae

EGGS

Diameter	1.31-1.66 mm
No. of oil globules	One, at vegetal pole
Oil globule diameter	0.27-0.46 mm
Yolk	Segmented
Envelope	Pustules (pronounced raised bumps on inner surface)
Hatch size	
Incubation time/temp.	
Pigment	

Diagnostic characters

- Pustules more pronounced than in bathylagid eggs

LARVAE

Preanal length	76-84% SL
Length at flexion	>9 mm SL
Length at transformation	25-30 mm SL (prolonged) ^b
Sequence of fin development	Caudal, dorsal and anal, pectorals, pelvics
Pigment	

- Internal head pigment
- Series of ventral trunk blotches extending from pectoral fin to end of gut
- 1-2 large blotches postanal with a large caudal blotch
- Blotches expand with development (see figure)

Diagnostic characters

- Transverse rugae lining gut
 - Fin rays form in finfold, away from body margin
- Distinguished from *Nansenia candida* by
- Presence of internal head pigment
 - Caudal pigment on preflexion larvae
 - Fewer spots over gut

^aFitch and Lavenberg 1968

^bTransformation: Morphological changes (deepening of body, lengthening of snout, enlargement of eye) and folding of anterior gut to form stomach, along with masking of larval pigment, occur at 25-30 mm. Pelagic juveniles may occur at 50-100 mm.

LIFE HISTORY

Range	S. California, 32-34°N, to Bering Sea, 54-66°N
Ecology	Epi- and mesopelagic, 60-1000 m
ELH pattern	Oviparous, pelagic eggs, pelagic larvae
Spawning	Season: Area: Mode: Migration:
Fecundity	Range/function:
Age at first maturity	
Longevity	

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	
No. of oil globules	
Oil globule diameter	
Yolk	Segmented
Envelope	Pustules on inner surface
Hatch size	
Incubation time/temp.	
Pigment	

Diagnostic characters**LARVAE**

Preanal length	59-61% SL
Length at flexion	
Length at transformation	Larval characters visible to 50 mm SL
Sequence of fin development	Caudal, dorsal, anal, pectorals, pelvics
Pigment - Large isolated melanophores	
• Preflexion larvae: Pigment on lower jaw, midgut, and tail	
• Flexion larvae	
—Opposing dorsal and ventral midline melanophores	
—Large melanophores on head and pectoral fin base	
—Large lateral blotch at base of caudal fin	

Diagnostic characters

- Gut shorter (usually only 50% SL) than in other species
- Eye rounder and larger than in other bathylagids (not stalked)
- Fin rays develop in finfold, away from body margin
- Distinguished from other bathylagids without eyestalks by
- Large isolated spots
- *B. wesethi* has a series of melanophores along hypaxial region, large eye, and spots posteriorly along dorsal midline
- *Leuroglossus* spp. larvae have smaller eyes and no dorsal spots

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	0.92-1.1 mm
No. of oil globules	>10, usually coalesce to 1 in late stage ^d
Oil globule diameter	
Yolk	Segmented
Envelope	Pustules on inner surface
Hatch size	
Incubation time/temp.	
Pigment	• Unpigmented

Diagnostic characters

- Lack of pigmentation in late-stage eggs

LARVAE

Preanal length	81-90% SL
Length at flexion	
Length at transformation	
Sequence of fin development	Caudal, dorsal, anal, pectorals, pelvics
Pigment	- Linear series of small melanophores
	• Series of melanophores develops on hypaxial myomeres
	• Epaxial melanophores limited to posterior body
	• Series along posterior gut
	• May occur on urostyle at sizes <7.9 mm SL

Diagnostic characters

- Eye stalks
- Distinguished from other bathylagids with linear series of smaller melanophores by
- Posterior gut melanophores larger and fewer
 - Anterior region of gut lacks pigment
 - Epaxial myomere series limited to posterior region
 - Fin rays form in finfold, away from body margin
- Distinguished from *B. bericoides* by
- Small *B. bericoides* larvae are unavailable but presumably eye stalks are longer at comparable stages
- Distinguished from *B. pacificus* by
- Series of melanophores as opposed to isolated spots

Pigment

- Series of melanophores on each hypaxial myomere
- Heavy embedded blotch at pelvic fin base; expands dorsad and ventrad
- Caudal blotch
- Above terminal section on gut ventral to liver
- Lower jaw

Diagnostic characters

- Deeper body and shorter gut than *B. exilis* and *Dolichopteryx longipes*
- Head with pronounced hump or bend at nape
- Tubular eyes directed dorsally
- Number of myomeres (34-37)

Figure A, NWAFC original (B. Vinter); B-C, Chapman 1939.

Members of the slickhead family are found worldwide in the deep sea, with six species in six genera found within the limits of this study area. Adults occur at depths of 45 to 5500 m but are primarily taken in hauls near the ocean bottom below 600 m. Juveniles occur in midwater (Fitch and Lavenberg 1968). Reproductive characteristics are unknown. Little information on alepocephalid early-life-history stages has appeared since Beebe (1933) in which they were found to hatch from large eggs (3-4 mm) and have direct development. There is no close relationship between alepocephalids and argentinoids because alepocephalids have large eggs, direct development, and share no specialized ontogenetic characters with argentinoids (Ahlstrom et al. 1984b).

Table 6

*The NWAFC meristic database was updated by Sazonov 1981.

Tubeshoulders are found in all oceans, and five species in four genera are known in the Northeast Pacific Ocean and Bering Sea (Matsui and Rosenblatt 1987). Adults are commonly taken in midwater trawls but have been found at the surface (at night) to below 1000 m (Fitch and Lavenberg 1968). Little is known of their reproduction and early life history except that juveniles of *Sagamichthys abei* migrate upward at night to within 200 m of the surface to feed (Hart 1973).

*Taxonomy and meristic data from Matsui and Rosenblatt (1987). The northernmost record of *Mirorictus taningi* (reported also as *Normichthys campbelli*) is 35°N but it may occur further north.

Smelts are confined to the Northern Hemisphere, and seven species in six genera are found in the northeastern Pacific. Some species spawn intertidally, others are anadromous. Spawning is protracted and en masse. Spent fish return to deeper water except for *Thaleichthys pacificus*, which experiences high, though not complete, mortality after spawning (Garrison and Miller 1982). Osmerid eggs are generally 0.80-1.1 mm, strong to feebly adhesive, and have numerous oil globules. The adhesive membrane results from the rupturing of an outer "chorion" during spawning which turns out and onto the substrate (Hearne 1983, 1984). In general, larval characteristics include an elongate body shape, gut 75% of standard length, subterminal mouth, conspicuous choroid fissure, stalked pectorals, no dorsal melanophores, a single row of melanophores along the ventral midline of the gut, and a single row of melanophores on the ventral midline of the tail (Hearne 1984). All osmerid larvae possess a single midventral row of melanophores below the gut. *Spirinchus starksi* larvae have a greater number of ventral melanophores than *Spirinchus thaleichthys* or *Thaleichthys pacificus* (Hearne 1983). Myomere counts may be of additional use. Osmerids are the most abundant larvae in the nearshore waters (0-20 km) off Oregon; usually >50% of the larvae collected from January through June are osmerids (B. Mundy, NMFS Southwest Fish. Cent., Honolulu Lab., Honolulu, HI 96822-2396, pers. commun., 1 Oct. 1986.). Presently, it is possible to identify only one of these larvae to genus or species. A complete developmental series of *Mallotus villosus* is known. They are common in our ichthyoplankton collections off Oregon, Washington, and in the Gulf of Alaska.

Range	Washington, 46-48°30'N, to Arctic, not specific
Ecology	Nearshore shelf pelagic, 0-200 m; ^a 750 m ^b
ELH pattern	Oviparous, demersal attached eggs, pelagic larvae
Spawning	Season: Fall (British Columbia); ^c spring (Bering Sea) ^d Area: Gravel beaches ^c Mode: Schools ^c Migration:
Fecundity	Range/function: 3000-6600 (British Columbia) ^c
Age at first maturity	2+ yr ^e
Longevity	>3 yr ^f

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	1 mm
No. of oil globules	
Oil globule diameter	
Yolk	
Envelope	Adhesive
Hatch size	3-6 mm
Incubation time/temp.	
Pigment	

Diagnostic characters**LARVAE**

Preanal length	~75% SL
Length at flexion	After yolk absorption, ~7-8 mm SL
Length at transformation	
Sequence of fin development	Probably caudal, dorsal, anal, pelvics, pectorals
Pigment	<ul style="list-style-type: none"> • Single row of melanophores along ventral gut midline • Single row of postanal ventral melanophores developing into double row (ventral view)

Diagnostic characters (see Table 4)

- Distinguished from clupeiforms by
- Higher number of myomeres (62-73)
 - Pigment: Single rather than double row of mid-ventral melanophores below gut
 - Greater gut length (75% SL)
 - Presence of adipose fin
- Distinguished from other osmerids by
- Combination of greater number of pectoral fin rays (16-21) and anal fin rays (16-23)

Stomiiformes

Fishes of the order Stomiiformes are mostly tropical to temperate, with many being deep-sea. This highly diverse order contains 9 families, 53 genera, and about 248 species (J. Nelson 1984). A total of 6 families, 12 genera, and 22 species are found within the study area. Body forms among stomiiforms range from eel-like (idiacanthids) to deep and extremely compressed (sternoptychids). Most species have luminescent organs, teeth on both premaxilla and maxilla, mouth extending past the eye, an adipose fin, and a dark-brown or black color (primarily silver in *Gonostomatidae* and *Sternoptychidae*). Presently, there is no consensus on the relationships within the order (Weitzman 1974, Fink and Weitzman 1982, Ahlstrom et al. 1984c, Fink 1984). Herein, we treat the gonostomatids and sternoptychids together, and the chauliodontids, melanostomiids, malacosteids, and idiacanthids together. For convenience, we will call the former families the gonostomatoids, and the latter the stomioids, without phylogenetic implications. The identification of gonostomatoid larvae requires a knowledge of developmental data from larvae, juveniles, and adults (including fin rays, teeth, and photophores). Of importance are pigment patterns, position of dorsal and anal fins (caution must be used, since positions change with growth), presence of an adipose fin, and photophores (number, pattern, and sequence of development) (Ahlstrom et al. 1984c). In addition to pigment patterns and meristic and photophore characters, gut structure (trailing or not) is an important feature to consider in the identification of stomioids.

Families in study area: **Gonostomatidae**
Sternoptychidae
Chauliodontidae
Melanostomiidae
Malacosteidae
Idiacanthidae

STOMIIFORMES

Table 9
Definitions of alphabetical symbols used for designating photophores in deep-bodied sternoptychids and other stomiiform fishes
(Ahlstrom et al. 1984c, in part).

Code	Definitions
Gonostomatoids	
SO	Symphyseal photophores (organs) located at tip of lower jaw.
Orb	Photophores associated with the eye located anterior and posterior of <u>orbit</u> .
Op	Photophores on <u>opercle</u> series generally three, coded as follows 1/(1+1).
Br (BRP)	Photophores located on the <u>branchiostegal</u> membranes.
Is (I)	Photophores located on the <u>isthmus</u> .
IP	Photophores of the ventral series found from the <u>isthmus</u> to the base of the <u>pectoral</u> fin.
PV	Photophores of the ventral series found from the <u>pectoral</u> fin base to the pelvic (<u>ventral</u>) fin base.
VAV	Photophores of the <u>ventral</u> series found from the pelvic (<u>ventral</u>) fin base to the <u>anal</u> fin base.
AC	Photophores of the <u>ventral</u> series found from the <u>anal</u> fin base to <u>caudal</u> fin base.
IC	Summary of photophores of the ventral series from the <u>isthmus</u> to <u>caudal</u> fin base (IP+PV+VAV+AC).
IV	Summary of photophores of the ventral series from <u>isthmus</u> to pelvic (<u>ventral</u>) fin base (IP+PV).
OV	Photophores of the lateral series from the <u>opercle</u> to pelvic (<u>ventral</u>) fin base.
VA (VALA)	Photophores of the lateral series from the pelvic (<u>ventral</u>) fin base to the <u>anal</u> fin base.
OAA	Summary of photophores of OV plus VA series.
OA (OAB)	Summary of lateral photophores from the opercle to anal fin base (OV+VA).
OAC (OC)	Entire lateral series on body sides just dorsal to ventral series and extending from <u>opercular</u> border, or just medial to it, over <u>anal</u> fin to <u>caudal</u> fin base.
ODM	Photophores (organs) found <u>dorsal</u> to the lateral <u>midline</u> (found only in <i>Gonostoma gracile</i>).
Deep-bodied Sternoptychids	
SO	<u>Subopercle</u> photophore which is equivalent to posteriormost photophore in opercular series of gonostomatoids.
PO	<u>Photophore</u> located anterior to <u>orbit</u> .
PTO	<u>Photophore</u> located posterior to <u>orbit</u> and may be equivalent to upper photophore of opercular series of gonostomatoids.
PRO	<u>Preopercular</u> photophore, used for PO photophore dorsal to ventral limb or preopercle.
Br	Same as gonostomatoid definition.
Is	Same as gonostomatoid definition.
AB	Photophores of ventral series located <u>abdominally</u> between pectoral fin base and pelvic fin base and equivalent to PV in gonostomatoids, plus a few posterior photophores of the IP series.
PAN	<u>Photophores</u> found <u>anterior</u> to <u>anal</u> fin and may be equivalent to VAV or VA in gonostomatoids.
AN	Photophores found above <u>anal</u> fin.
SC	Photophores found on lower (<u>sub</u>) <u>caudal</u> peduncle. Together with AN group may be equivalent to AC in gonostomatoids.
SAB	Photophores located above (<u>supra</u>) to the <u>abdominal</u> series and may be equivalent to VA in gonostomatoids.
SP	Photophores located above (<u>supra</u>) the <u>pectoral</u> fin and may be equivalent to OV in gonostomatoids.
SAN	Photophores located above (<u>supra</u>) to <u>anal</u> photophores and equivalent to part of AC series.

Table 10
Photophore distribution in selected gonostomatoid genera (Ahlstrom et al. 1984c, in part). See Table 9 for photophore definitions.

^aE.H. Ahlstrom notes

^bRecords from north of British Columbia are questionable (A.E. Peden, Brit. Col. Prov. Mus., Victoria, B.C., Canada V8V 1X4, pers. commun., 22 Jan. 1987).

This worldwide genus of lightfishes may constitute the most abundant genus of fish in the sea. These small (to 80 mm) bathypelagic fishes are found most commonly at depths of 300 m and greater and have been found as deep as 5300 m. Very little information on life history is available. The eggs are unknown but larvae are common in offshore tropical and temperate areas. *Cyclothone* spp. larvae are discussed at the generic level since only partial series are available for the five species in the study area. Gorbunova (1982a) described the larvae of eight species from the Pacific including four from the study area (all species except *C. atraria*). The descriptions of *C. acclinidens*, *C. pallida*, and *C. pseudopallida* by Gorbunova (1982a) have been questioned by Ozawa and Oda (1986) who described the larvae (>7 mm SL) of five species of *Cyclothone* (all species from the study area except *C. signata*). Since preflexion larvae and transforming larvae linking larval series to adults are generally unavailable, Ozawa and Oda (1986) discussed the need for further investigation.

Preanal length for *Cyclothone* spp. larvae is about 50% SL. Lengths at flexion and transformation are 4-5 mm SL and about 14 mm SL, respectively. Caudal and dorsal fins form first, followed in sequence by the anal, pelvic, and pectoral fins. Photophores are described in Table 10.

Pigment characters for *Cyclothone* spp., based on described species, include

- 2-3 spots along gut with posteriormost spot at anus (sometimes more spots in larger specimens)
- One spot at cleithral symphysis
- Pigment on swimbladder
- Lateral series posterior to pectoral fins, ending prior to swimbladder
- Series over anal fin base (varies from ~5-12 spots and may or may not be evenly spaced; number and spacing of series may be species-specific)
- Some species develop dorsal series similar to anal base series
- Spots at base of anal fin pterygiophores
- Spots usually appear above and below urostyle and in hypural area

Diagnostic characters for *Cyclothone* spp. larvae include

- Distinct dark streak or intense melanophore over and parallel to parhypural on caudal fin base
- Pigmentation over gut and along ventral margin of tail
- Anal fin origin opposite dorsal fin or slightly behind (no ontogenetic movement)
- Conspicuous swimbladder
- No adipose fin
- Larvae generally elongate

Diagnostic characters for species

- *C. acclinidens* (melanophore on dorsal part of tail end)
- *C. pseudopallida* (predorsal melanophores 2-4, see figure)
- *C. atraria* (predorsal melanophores 6 or 7, see figure)
- *C. pallida* (predorsal melanophores 9-12, see figure)
- *C. signata* (no melanophore on dorsal part of tail end, and no predorsal melanophores)

Distinguish from *Gonostoma*

- See Tables 10-12
- Fewer anal fin rays (16-21 vs. 21-31)
- Fewer vertebrae (29-33 vs. 37-40)
- SO photophore absent
- Caudal pigment (present in *Gonostoma atlanticum* but not in *G. gracile*)

Larger postflexion larvae, which differ greatly from adults, undergo a metamorphic stage during which most of the photophores become pigmented simultaneously, the anterior portion of the body shortens, and the anus changes position from near the anal fin to nearer the ventral fin bases.

Diagnostic characters**LARVAE (*G. gracile*)**

Preanal length	
Length at flexion	
Length at transformation	
Sequence of fin development	Caudal, dorsal and anal, pectorals and pelvics
Pigment	
• Internal head pigment	
• Swimbladder and peritoneum	

Diagnostic characters

- G. gracile* distinguished from other *Gonostoma* spp. by
- Anal fin origin extremely in advance of dorsal fin origin
- G. gracile* distinguished from *G. atlanticum* by
- Lack of pigment on caudal peduncle and body surface
- G. atlanticum* distinguished from *Cyclothone* spp. by
- Caudal and ventral pigment
 - Swimbladder position

Photophores (see Table 10)

In *G. gracile* and *G. atlanticum*, photophores develop as a group. This differs from other species of *Gonostoma* where photophores develop gradually.

GONOSTOMA
Gonostoma atlanticum

Gonostoma gracile

Figure A, Ahlstrom et al. 1984c (after Ahlstrom 1974); B–E, Kawaguchi and Marumo 1967 (western Pacific specimens).

STERNOPTYCHIDAE

Found in all temperate and tropical seas, hatchetfishes are represented in the northeastern Pacific by seven species in three genera. Adults are found 100-5000 m below the surface (Schultz 1961). Sternoptychid eggs and larvae are planktonic, constituting the third most abundant family in the ichthyoplankton of open ocean waters (after myctophids and gonostomatids) (Ahlstrom 1972, Loeb 1979). *Argyrolepecus hemigymnus* has eggs ranging from 0.92 to 1.04 mm. The yolk is coarsely segmented and contains one oil globule (Ahlstrom 1974). Development of sternoptychids is distinctly divided into two periods (Sanzo 1935): Larval period, and the period of metamorphosis marked by a sharp reduction in body length, change in shape, and photophore and fin-ray development. Distribution and patterns of photophores, especially their sequence of development, are instrumental in larval identification. The following characters may aid in distinguishing between the three sternoptychid genera in the study area (see Tables 13-14).

	<i>Argyrolepecus</i>	<i>Danaphos</i>	<i>Sternoptyx</i>

Length at flexion
Length at transformation
Sequence of fin development Caudal and pectorals, dorsal and anal, pelvics
Pigment

- Initially, appears anteriorly on body in patches and, with development, increases posteriorly
- Spot on peduncle does not appear as early as *A. affinis*, first appearing as a patch in larvae >13 mm SL

Diagnostic characters

- Spines: Upper preopercular spine is developed (pointed slightly upward) and short frontal crests are present
- Distinguished from *A. affinis* and *A. hemigymnus* by
- Combination of nine dorsal spines and SAB, PAN, AN, and SC photophores not in continuous line

Figures A–C, Belyanina 1984.

LIFE HISTORY

Range	South of southern California to Brit. Col., 48°30'-55°N ^a
Ecology	Meso- and bathypelagic
ELH pattern	Oviparous, eggs probably pelagic, pelagic larvae
Spawning	Season: Area: Mode: Migration:
Fecundity	Range/function:
Age at first maturity	
Longevity	

^a *S. diaphana* only to Oregon, 42-46°N.

^b Although not well documented, geographic variation among and within species is clearly present.

^c A dramatic change in morphology occurs at transformation. Elongate larvae become deep-bodied juveniles. Body length cannot be associated with development.

^d Badcock and Baird (1980) cite a personal communication from E.H. Ahlstrom stating that neither of the two forms of *Sternoptyx* spp. from the study area have caudal pigment. A figure of *S. pseudodiaphana* is provided as an example of an early larva with caudal pigment.

Ref: Badcock and Baird 1980, Belyanina 1983.

EARLY LIFE HISTORY DESCRIPTION

EGGS

- Diameter
- No. of oil globules
- Oil globule diameter
- Yolk
- Envelope
- Hatch size
- Incubation time/temp.
- Pigment

Diagnostic characters

LARVAE - Genus^b

- Preanal length
- Length at flexion
- Length at transformation 6-14 mm SL^c
- Sequence of fin development Pectorals and caudal, anal, dorsal and pelvics
- Pigment
 - Head and tip of lower jaw
 - Peritoneum, becoming embedded with development
 - Presence/absence of pigment on caudal peduncle; according to Belyanina (1983) some specimens of *S. diaphana* have pigment whereas specimens of *S. pseudobscura* have none^d

Diagnostic characters

- Prior to metamorphosis, larvae of the two species are indistinguishable; both with spiny ridges on frontal and parietal bones, opercular and post-temporal spines
- Distinguish *S. pseudobscura* juveniles from *S. diaphana* by
 - Rounder body
 - Posterior anal pterygiophores longer
 - SAN higher in position

Photophores (see Table 10)

Order of development in *Sternoptyx* spp. larvae: SO, Br2, AB7, I4, SP3, PTO, AN1 followed by PAN, SC, PRO, and SAN in early juveniles; finally SC.

EARLY LIFE HISTORY DESCRIPTION

EGGS

- Diameter
- No. of oil globules
- Oil globule diameter
- Yolk
- Envelope
- Hatch size
- Incubation time/temp.
- Pigment

Diagnostic characters

LARVAE

- Preanal length** <50% SL (short gut)
- Length at flexion**
- Length at transformation** ~45-50 mm SL
- Sequence of fin development**

Pigment

- Concentrated on preanal body in area below eye and over gut; smaller larvae generally unpigmented except over peritoneum

Diagnostic characters

- Larvae elongate
 - Photophores begin formation ~16.5 mm SL (see Table 15)
 - Photophores in clusters with common bases
 - Metamorphosis gradual with the initial formation of photophores in the BR and PV groups
- Distinguished from *Argyropelecus* spp. and *Sternoptyx* spp. by
- Long anal fin (24-25 fin rays) and short dorsal fin (6 fin rays)

Ref: Ahlstrom 1974, Ahlstrom et al. 1984c.

Table 15
Development of photophores in *Danaphos oculatus* (Ahlstrom et al. 1984c). * See Table 9 for definitions of photophore groups.

Size (mm SL)	Photophore groups								
	ORB	OP	SO	BR	IP	PV	VAV	AC	OA
Adult	1	3	0	(6)	(3)+(4)	(11)	(5)	(3)+16+(4)+1	6

Ecology	Epi-, meso-, and bathypelagic, 76-4231 m
ELH pattern	Oviparous, pelagic eggs, pelagic larvae
Spawning	Season: Area: Mode: Migration:
Fecundity	Range/function:
Age at first maturity	
Longevity	>8 yr ^a

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	2.69-3.17 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Segmented
Envelope	Smooth, clear
Hatch size	6-7 mm SL

Incubation time/temp.**Pigment**

- Pigment in caudal region of yolksac larvae, but soon disappears

Diagnostic characters

- Wide perivitelline space, 0.5 mm
- Yolk segmented
- Large egg size

LARVAE

Preanal length	Long, >75% SL
Length at flexion	>15 mm SL
Length at transformation	Adult ~35-46 mm SL ^b
Sequence of fin development	Dorsal, anal, and pelvics form late in postflexion larvae in adult position

Pigment

- According to Kawaguchi and Moser (1984), unpigmented except for fan-shaped caudal finfold in yolksac larvae. We have not collected any yolksac larvae and therefore have not observed this pigment. A figure of a yolksac *C. sloani* is included for comparison only.

Diagnostic characters

- Morphology: Small head, elliptical eyes, long gut, slender body
- Median finfold shape
- Lack of pigmentation
- Slightly trailing gut

^aFitch and Lavenberg 1968^bMarked shrinkage at transformation.

Ref: Kawaguchi and Moser 1984.

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	1.39-1.54 mm
No. of oil globules	One
Oil globule diameter	0.3-0.4 mm
Yolk	Segmented
Envelope	Smooth
Hatch size	5 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

- Oil globule large and ventral
- Egg round

LARVAE

Preanal length	>75% SL
Length at flexion	
Length at transformation	44-49 mm SL
Sequence of fin development	Caudal, dorsal and anal, pectorals and pelvics
Pigment	

- In early larvae, one melanophore per myomere along dorsum and 1-3 melanophores on hypaxial myosepta; postflexion larvae gradually lose the dorsal then ventral melanophores
- Lower jaw, isthmus, pectoral fin base, cleithrum, gut terminus, caudal peduncle

Diagnostic characters

- Morphology: Body elongate and flat, gut slender, finfold moderate
 - Pectoral fin lost at transformation
 - Decrease in pigment with development
 - No trailing gut
 - Finfolds unpigmented
- Distinguished from *Chauliodus macouni* (p. 108) by
- Presence of pigment
 - Posterior position of dorsal fin (origin of dorsal and anal fin opposite each other)

EARLY LIFE HISTORY DESCRIPTION

EGGS

- Diameter**
- No. of oil globules**
- Oil globule diameter**
- Yolk**
- Envelope**
- Hatch size**
- Incubation time/temp.**
- Pigment**

Diagnostic characters

LARVAE

- Preanal length**
- Length at flexion**
- Length at transformation** 35-70 mm SL
- Sequence of fin development** Caudal, dorsal and anal, pectorals,^b pelvics^c
- Pigment - Genus**
 - Melanophore on posterior margin of each hypaxial myomere
 - Isthmus
 - Series along trailing gut

Diagnostic characters - Genus

- Morphology
 - Extremely slender body
 - Elongate flat head
 - Elliptical eyes on stalks with cartilaginous support rods (27% BL)
 - Trailing gut
 - Small finfold
- Distinguished from *I. fasciola* by
 - Longer eye stalk and trailing gut

Since specimens are often damaged and pigment patterns are similar, the two species may be difficult to separate. In addition to the above characters, the two species differ in size at various stages of development. *I. antrostomus* larvae are 4.5-71.0 mm SL, transforming at sizes >67 mm SL. *I. fasciola* larvae are 16-28 mm SL, transforming at sizes between 35 and 48 mm SL.

Figures A–F, Beebe 1934 (North Atlantic specimens).

Scopelomorpha: Aulopiformes
Myctophiformes

The myctophiforms (Myctophidae and Neoscopelidae) and aulopiforms (J. Nelson 1984) are treated together here. According to J. Nelson (1984), these orders consist of 14 families, and about 75 genera with 429 species. Although several families are benthic (e.g., synodontids), most families consist of deep-sea, pelagic, and benthopelagic forms. Many families (not myctophids) are synchronous hermaphrodites. The diverse early-life-history stages are generally well known and can be distinguished by morphological characters (head, gut, body) and pigment patterns. Additionally, photophore patterns and development are especially helpful in myctophid fishes, while gut pigment (i.e., number and development of peritoneal patches) is an important character distinguishing some of the other families.

Families in study area: **Scopelarchidae**
Notosudidae
Synodontidae
Bathysauridae
Paralepididae
Anopteridae
Alepisauridae
Neoscopelidae
Myctophidae

Spawning	Season: Area: Mode: Synchronous hermaphrodites ^c Migration:
Fecundity	Range/function:
Age at first maturity	
Longevity	

^a *B. linguoidens* only to Oregon, 42-46° N.^b *B. dentata* only, *B. linguoidens* larvae are incompletely known.^c Johnson 1974a^d Larvae of *Benthalbella* spp. are unique among scopolarchids in achieving a large size (50-100 mm SL) while retaining a purely larval form and then exhibiting a very rapid transformation. The largest known larvae of *B. linguoidens* = 85.5 mm SL, and may transform at larger sizes than *B. dentata*. Transformation is complete when peritoneal pigment first appears (uniformly in mesentery dorsal to gut from between pectoral fin bases to behind pelvic fins).

Diagnostic characters**LARVAE^b**

Preanal length	Anus moves posterior during transformation
Length at flexion	
Length at transformation	50 mm SL ^d
Sequence of fin development	Caudal; dorsal, anal, and dorsal part of pectoral; pelvics; ventral part of pectoral

Pigment

- No "accessory" pigment
- No "dermal" pigment; develops in transforming larvae and persists in adults

Diagnostic characters

- Gut expansion (in larvae, anus anterior to pelvic fin base but moves posterior during transformation)
- Pelvic fin origin ahead of dorsal fin origin
- Adipose fin develops posterior to anal fin
- No peritoneal pigment in larvae

B. linguoidens

B. dentata

Figures A–C, Johnson 1974a.

Diagnostic characters

LARVAE^c

Preanal length 70% SL

Length at flexion

Length at transformation >83 mm SL (gradual)^d

Sequence of fin

development

Pigment

- Peritoneal patches, about five; about six short bars laterally on gut
- About 17 vertical bars along body, 8 shorter bars in interspaces between vertical bars
- Several spots on head and fin rays

Diagnostic characters—Family

- Elongate fins
- Anterior placement of dorsal and pelvic fins
- Raised dorsal and anal fin bases
- Long gut terminating in front of anal origin
- Pigment: Peritoneal (5-6 sections) and lateral bars

^aOkiyama 1984

^bWenner 1978

^c*B. mollis* larvae originally described as “*Macristium*” larvae (Johnson 1974b). An illustration of *B. ferox* is provided for comparison and to show fin rays intact.

^dChanges at transformation include shortening of fins, expansion of gape, backward shift of dorsal fin origin, and darkening of body surface, oral cavity, and peritoneum. According to Sulak et al. (1985), the large sizes attained by these larvae suggest a long oceanic existence prior to transformation.

Figure A, Johnson 1974b (Gulf of Mexico specimen); B, Marshall 1960 (Atlantic specimen).

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	1.33-1.44 mm
No. of oil globules	None
Oil globule diameter	
Yolk	
Envelope	Hexagonal surface
Hatch size	<4.7 mm SL
Incubation time/temp.	
Pigment	

- Unpigmented until late stage of development when pigment first appears along dorsal midline
- Few scattered yolksac spots
- Late-stage embryo resembles newly hatched larva with distinctive pigment along gut

Diagnostic characters

- Hexagonal surface similar to *Pleuronichthys coenosus* (p. 616) except hexagons are wider (0.047 mm vs. 0.035 mm) and irregularly arranged^b

LARVAE^c

Preanal length	>50% SL
Length at flexion	~10.5 mm SL
Length at transformation	
Sequence of fin development	Caudal, anal, dorsal, pectorals, pelvics

Pigment

- Seven evenly spaced pairs of “peritoneal patches” which form gradually
- Spot on postanal ventral midline midway between anus and tail
- Spot in area where hypurals are forming

Diagnostic characters

- Distinctive peritoneal patches (seven)
- Preanal finfold
- Deeper body than other *Synodus* spp.

^aDuring “El Niño” years, adults occur as far north as Puget Sound, Washington. Postflexion larvae were collected off Oregon during the strong El Niño summer of 1982 (B. Mundy, NMFS Southwest Fish. Cent., Honolulu Lab., 2570 Dole St., Honolulu, HI 96822, pers. commun., 1 Oct. 1986).

^bSee Sumida et al. 1979.

^cData on preflexion and postflexion larvae are from E.H. Ahlstrom notes. Illustrations are unavailable.

No. peritoneal patches (flexion larvae)	3	1	2
(postflexion larvae)	7	12	3
No. myomeres	84-87	72-74	76-83

^aOkiyama 1984

^bPeritoneal pigment patches are sequentially formed with gradual lengthening of the gut. The number of patches (called "sections" by Okiyama 1984) may be species-specific. In general, these patches develop by 5-10 mm SL and persist until 15-45 mm SL. Other characteristic paralepidid pigment may include dorsum of body, caudal peduncle, and caudal and pectoral fins.

^cGeneral morphological characters in paralepidids are a long compressed body, short gut increasing in length with development, head increasing in relative size with development, elongate snout, well-developed preanal finfold, and eyes initially ovoid, becoming round with development.

MYCTOPHIDAE

Lanternfishes are worldwide in distribution, having 32 genera with 235 species found from the Arctic to the Antarctic. Myctophids generally have large eyes, large terminal mouths, photophores, and a black body color. In the Northeast Pacific, 20 species occur within two subfamilies: Myctophinae and Lampanyctinae. Most of the species (13) are members of the Lampanyctinae.

Myctophids are oviparous and presumably all produce planktonic eggs (Moser et al. 1984a). Eggs of only two species have been described: *Electrona rissoi* by Sanzo (1939) and *Lampanyctodes hectoris* by Robertson (1977). Eggs of both species are small (<1.0 mm), possess a single large oil globule, segmented yolk, smooth chorion, and at least *Lampanyctodes* eggs possess a fragile chorion. We have identified several types of myctophid eggs with these characteristics, in particular a fragile chorion. At least two of these types are probably *Diaphus* and *Stenobranchius* (based on egg characters and the presence of yolksac larvae of those species in the same samples).

The larval photophore complements and the sequence of appearance of photophores are useful characters. Most myctophids develop the Br2 during the larval period (in the Northeast Pacific the only exception is *Taaningichthys*). The Br2 is located posteroventral to the orbit but during transformation assumes a position beneath the orbit on the branchiostegal membrane. Three myctophine genera and eleven lampanyctine genera develop additional photophores during the larval period, with the Br2 always first to appear (Moser et al. 1984a). Of these 14 genera, only 4 are represented in our study area: *Ceratoscopelus*, *Lampadena*, *Diaphus*, and *Notoscopelus*.

The taxonomic section on myctophids here is arranged according to the intrafamilial classification of the group (Table 19), since certain larval characters reflect this classification (e.g., larval eye shape).

Subfamily Myctophinae	(Eyes elliptical)
Tribe Electronini	
	<i>Electrona rissoi</i>
	<i>Protomyctophum crockeri</i>
	<i>Protomyctophum thompsoni</i>

PHOTOPHORE GROUP TERMINOLOGY

Moser and Ahlstrom 1972.

MERISTICS

Vertebrae	Total: 32-X-34
	Precaudal: X-X-X
	Caudal: X-X-X
Branchiostegal rays	8-8-8
Caudal fin	6-8, 10+9, 6-7
Pelvic fin	Abdominal
	R: 8-8-8
Dorsal fin	R: 13-X-15
Pectoral fin	R: 13-X-16
Anal fin	R: 18-19-20
Gill rakers	U: 8-X-9 L: 18-X-21

LIFE HISTORY

Range	South of southern California to Oregon, 42-46°N
Ecology	Epi- and mesopelagic
ELH pattern	Oviparous, pelagic eggs, pelagic larvae
Spawning	Season: Area: Mode: Migration:
Fecundity	Range/function:
Age at first maturity	
Longevity	

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	0.80-0.84 mm
No. of oil globules	One
Oil globule diameter	0.28 mm
Yolk	Segmented
Envelope	Smooth, fragile
Hatch size	
Incubation time/temp.	
Pigment	

Diagnostic characters**LARVAE**

Preanal length	50% SL, with development 50-75% SL
Length at flexion	6.2-7.0 mm SL
Length at transformation	~10 mm SL
Sequence of fin development	Caudal, pectorals, anal, dorsal, pelvics

Pigment

- Lower jaw symphysis (see 7.9 mm)
- Pectoral fin blade (see 6.3 mm)

Diagnostic characters

- Photophores: Early Br2, usually forms at transformation in other species
- Morphology: Body moderately slender, head large
- Gut saccular, s-shaped
- Space between anus and anal fin origin but not as large as in *Protomyctophum* spp.
- Eyes very narrow
- Transforms earlier than most myctophids (9-10 mm SL)

Distinguished from other myctophids with elliptical eyes by

- Pigment on lower jaw tip and pectoral fin
- Lack of pigment on postanal body

Figures A–D, Moser and Ahlstrom 1970.

Diagnostic characters**LARVAE**

Preanal length	<50% SL
Length at flexion	7.2-8.8 mm SL
Length at transformation	12-15 mm SL, as large as 18 mm SL
Sequence of fin development	Caudal, pectorals, anal, dorsal, pelvics
Pigment	<ul style="list-style-type: none"> • Preflexion larvae unpigmented • Large melanophore over gut • Postanal ventral melanophores in juveniles

Diagnostic characters

- Single spot over gut and lack of pigment elsewhere (flexion and postflexion larvae)

For Genus

Distinguished from other myctophids with elliptical eyes by

- Head small, body slender
- Gut short
- Wide space between anus and anal fin
- Larvae relatively lightly pigmented
- Eyes moderately narrow
- No enlarged fins

Distinguished from *P. thompsoni* by

- Lack of postanal ventral melanophores in preflexion larvae and presence of only one spot over the gut in larger larvae

Diagnostic characters

LARVAE

Preanal length	55% SL increasing with development to 80% SL
Length at flexion	8.0-11.0 mm SL
Length at transformation	>20.0 mm SL
Sequence of fin development	Pectorals, caudal, anal and dorsal, pelvics
Pigment	<ul style="list-style-type: none"> • Preflexion and flexion larvae <ul style="list-style-type: none"> —Dark band of pigment between olfactory and optic lobes of the brain —Blotch develops medially to each pectoral fin base —Two blotches on dorsal surface of gut merging into one with development —Three postanal body blotches —Median finfold, lower pectoral ray —Dorsal and ventral margins of caudal peduncle

Diagnostic characters

- Among largest myctophid larvae at transformation (>20.0 mm SL)
 - Morphology: Early larvae slender but relative body depth doubles in later stages
 - Only Br2 develops during larval period
- Distinguished from all other myctophids except *Tarleton-beania crenularis* by
- Enlarged median finfolds
- Distinguished from *T. crenularis* (p. 158) by
- Eye moderately narrow, no choroid tissue on ventral surface of eye
 - Pigment: Band on head between eyes

^aLarvae have six more pectoral fin rays than adults.

^bRange for larvae; adults widespread.

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter
No. of oil globules
Oil globule diameter
Yolk
Envelope
Hatch size
Incubation time/temp.
Pigment

Diagnostic characters

LARVAE^b

Preanal length	46% SL, with development 58-61% SL
Length at flexion	6.2-7.0 mm SL
Length at transformation	16.6-21.0 mm SL (may be larger)
Sequence of fin development	Caudal, pectorals, anal, dorsal, pelvics

Pigment

- Generally light pigment
- Pair of melanophores at each side of gut at point of divergence of the free terminal section (retained throughout but becoming embedded with development)
- Series (~11) of postanal ventral melanophores in early larvae, with development usually coalescing to a single spot in postflexion larvae

Diagnostic characters

- Photophores: Br2 (7.0 mm SL); Vn (7.8 mm SL); PLO (8.7 mm SL; develop and remain at pectoral fin base throughout larval period but at transformation they migrate dorsally to just below the lateral line); PO5 (9.0 mm SL); during transformation the remaining photophores develop sequentially
- Distinguished from other myctophids with round eyes by
- Eye elliptical in preflexion larvae (although not perfectly round, the eye is easily differentiated from the narrow eyes of larval Myctophinae)
 - Single spot at anus
 - Preflexion larvae with ~11 postanal ventral melanophores

^aPeden and Hughes (1986) report counts for the following meristic characters:

Precaudal vertebrae	16
Caudal vertebrae	20
Anal fin rays	15
Gill rakers	6-7+1+15

^bH.G. Moser, NMFS Southwest Fish. Cent., P.O. Box 271, La Jolla, CA 92038, pers. commun., 9 Jan. 1984. Illustrations of small larvae are unavailable. A figure of a preflexion larva of *C. warmingi* is included for comparison.

Diagnostic characters**LARVAE**

Preanal length	50% SL
Length at flexion	By 5-6 mm SL
Length at transformation	19.6 mm SL
Sequence of fin development	Caudal, pectorals, anal, dorsal, pelvics

Pigment - Genus^b
(Pigment for *L. urophaos* more restricted to dorsal and ventral midline)

- Brain, nape, gut, swimbladder
- Double row of large melanophores along dorsal midline with an opposing double row of postanal ventral midline melanophores
- Some with more numerous dorsal and ventral melanophores and internal pigment above the notochord

Diagnostic characters

- Photophores: Br2, PLO, PO5, and Vn+PO1 develop during larval period
- Distinguished from other myctophids with round eyes by
- Dorsal midline pigment anterior to anus

^aPeden and Hughes (1986) report counts of the following meristic characters:

Total vertebrae	38
Precaudal vertebrae	17
Caudal vertebrae	21
Gill rakers	5+1+12

^bDiscussion of pigment is based on genus, since illustrations of small larvae of *L. urophaos* are not available. Figures of a preflexion larva of *L. luminosa* are included for comparison.

Ref: Moser and Ahlstrom 1972; Moser et al. 1984a; H.G. Moser, NMFS Southwest Fish. Cent., P.O. Box 271, La Jolla, CA 92038, unpubl.

Figures A–B (A, dorsal view), Miller et al. 1979 (Hawaiian specimens); C–D, Moser and Ahlstrom 1972.

Of the four *Lampanyctus* species found in the study area, we can identify larvae of only *L. regalis* and *L. ritteri*. Generic characters include:

- Pigment above brain
- Myoseptal trunk pigment increasing during postflexion to cover most of anterior trunk at transformation
- Slender body; deepens and becomes robust in some species
- Deep head
- Gut short in early preflexion larvae; with development lengthens to midbody

The following meristic information may aid in identifying the four *Lampanyctus* species.

Species	Distribution	Vertebrae	Fins			
			Dorsal	Anal	Pectoral	Pelvic
<i>Lampanyctus fernalae</i>	N. Calif. - Oregon	36-38	12-14	16-18	12-14	8

Incubation time/temp.
Pigment

Diagnostic characters

LARVAE

Preanal length <50% SL
Length at flexion >5.3 mm SL, ~6-7 mm SL
Length at transformation >12.5 mm SL;
10-19 mm SL^b
Sequence of fin development Caudal, pectorals, anal, dorsal, pelvics
Pigment

- Gut melanophores: Early preflexion, lateral spots at pectoral fin base, midgut, and anus
- Series of postanal ventral melanophores (>15) in preflexion larvae which coalesce to 2 or 3 spots in postflexion larvae
- Postflexion: Above brain, nape, and embedded in trunk myosepta on each side of dorsal midline (not shown)

Diagnostic characters

- Photophores: Only Br2 forms in the larval period
- Distinguished from other myctophids with round eyes by
- Gut pigment: Three spots in preflexion larvae (pectoral fin base, midgut, and anus); with development spots are retained, although their position shifts posteriorly
- Series of postanal ventral melanophores (>15) in preflexion larvae
- Distinguished from *Diaphus theta* (p. 176) by
- Lack of pigment at caudal base
- Number of postanal ventral melanophores (>15): Preflexion larvae usually have >20; postanal ventral midline melanophores appear more embedded in *D. theta* (see figure)

S. nannochir larvae are unknown. The following meristic information may aid in identification.

Total vertebrae	36-38
Dorsal fin rays	13-14
Anal fin rays	14-16
Pectoral fin rays	9-10
Pelvic fin rays	8

Figures A–B, D, NWAFC originals (B. Vinter); C, Moser and Ahlstrom 1974.

MERISTICS

Pigment

- Preflexion: Jaw tips, above brain and swimbladder, lateral cleithral
- Postflexion: Lower jaw, hindbrain, nape, double row of melanophores along dorsal midline beginning at midbody, series along anal fin base, caudal fin base, pelvic and anal fin, internal notochord pigment on trunk

Diagnostic characters

- Photophores: Br2, PO5, Vn, and PLO develop during larval period
- Distinguished from other myctophids with round eyes by
- Morphology: Body moderately deep, head and eyes large
 - Midlateral and dorsal fin base pigment in postflexion larvae
 - Highest dorsal fin ray count among myctophids in study area (21-23)
 - Head pigment: Jaw tips, snout, opercle and brain

^a According to Peden and Hughes (1986) northern records of *N. resplendens* are probably *N. japonicus*.

^b H.G. Moser, NMFS Southwest Fish. Cent., P.O. Box 271, La Jolla, CA 92038, pers. commun., 9 Jan. 1984.

^c Both *N. resplendens* and *N. japonicus* are described and illustrated in Ozawa (1986d). Specimens from the eastern Atlantic are figured here, but, according to Ozawa (1986d), they may differ in pigmentation and in photophore development from specimens found in the Pacific.

Ref: Badcock and Merrett 1976; Moser and Ahlstrom 1972; Ozawa 1986d; Moser, unpubl.

Figures A–C, Badcock and Merrett 1976 (eastern Atlantic specimens); D, Ahlstrom and Moser 1974.

Gadiformes

Gadiform fishes include some of the most commercially important coldwater marine species in the world: the codfishes and their relatives. The order contains between 7 and 13 families, depending on the source, and well over 400 species. Fishes of this order are found worldwide and are generally bathypelagic (except for one freshwater species). Most species are elongate with some having long dorsal and/or anal fins. Pelvic fins are thoracic or jugular, and chin barbels are present in many. Although they are easily recognized and well studied, evolutionary relationships are poorly understood and most recent authors now propose a multiple origin for at least the Gadidae (Markle 1989). The early-life-history stages are well known, especially for the gadids and merlucciids, and have been studied for well over 100 years (Fahay and Markle 1984). Most eggs are pelagic, spherical, and have a single oil globule (lacking in some gadids). Larvae are commonly identified by their distinctive pigment patterns, coiled gut, and general tadpole shape. Morids, melanonids, and macrourids are less well known.

Families in study area: **Moridae**
Melanonidae
Merlucciidae
Gadidae
Macrouridae

MORIDAE

Morids are benthopelagic fishes distributed throughout the world's oceans and are represented by two species in two genera in the study area. Very little is known of the early life history of the codlings. For the few species described, eggs are 0.52-1.16 mm in diameter, have one oil globule, and a smooth chorion (Fahay and Markle 1984). The scarcity of small fish in bottom trawls indicates the very young, and perhaps eggs, are pelagic (Iwamoto 1975). Most morids have precocious pelvic fin ray development. Usually the pelvic fin rays are elongate and probably undergo some ontogenetic reduction. Figures of larvae of *Physiculus nematopus* and *Laemonema* sp. are provided for comparison, since larvae of species in our area are unknown.

Table 21
Meristic characters of family Moridae.

Taxon	Distribution	Vertebrae		Fins					Gill rakers			
		Precaudal (Total)	Caudal	First Dorsal	Second Dorsal	Anal	Pectoral	Pelvic	Caudal (Total)	Upper	Lower	Branchiostegals

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	1.07-1.18 mm (1.12 mm)
No. of oil globules	One
Oil globule diameter	0.27-0.34 mm
Yolk	May appear granular
Envelope	Clear, smooth
Hatch size	2.4 mm NL
Incubation time/temp.	3.1 d/16.6°C
Pigment	<ul style="list-style-type: none"> • On yolk • Characteristic late-stage patches on embryo

Diagnostic characters

- Pigment pattern
- Presence of oil globule
- Eye forms early during embryonic development

LARVAE

Preanal length	<50% SL
Length at flexion	~10 mm SL
Length at transformation	~30-35 mm SL
Sequence of fin development	Caudal, pelvics, 1st dorsal, 2nd dorsal and anal, pectorals

Pigment

- Preflexion larvae: One postanal bar, one large dendritic spot several myomeres posterior to anus; with development, bar becomes diffuse, postanal body pigment increases, especially dorsolaterally
- On head, crown, and snout; increasing with development
- Dorsolaterally on gut

Diagnostic characters

- Gadoid shape but absence of >1 distinct postanal pigment bar
- Two dorsal fins and one anal fin
- Specimens from Puget Sound and Straits of Georgia have pigmented pectoral rays

Figures A–F, Ahlstrom and Counts 1955.

The family Gadidae is represented in the Northeast Pacific Ocean and Bering Sea by five species: Walleye pollock, *Theragra chalcogramma*; Pacific cod, *Gadus macrocephalus*; Pacific tomcod, *Microgadus proximus*; saffron cod, *Eleginus gracilis*; and Arctic cod, *Boreogadus saida*. Identification of gadid larvae prior to 1980 was not possible. Gadid larvae collected during ichthyoplankton studies were routinely reported as "Gadidae." Recent taxonomic studies have continued since 1980 and have allowed the specific identification of all five species in the area (e.g., Matarese et al. 1981 and Dunn and Vinter 1984). Identification is based primarily on differences in pigmentation patterns and meristic characters. The available knowledge of the general early life histories of these five species was recently reviewed by Dunn and Matarese (1987).

Table 22
Characters useful in separating larvae of *Eleginus gracilis*, *Boreogadus saida*, *Gadus macrocephalus*, *Theragra chalcogramma*, and *Microgadus proximus* at specific size ranges (Dunn and Vinter 1984, in part).

Character	Size range (mm SL)	<i>E. gracilis</i>	<i>B. saida</i>	<i>G. macrocephalus</i>	<i>T. chalcogramma</i>	<i>M. proximus</i>
Pigment						
Preanal region						
Ventral gut	4.4-13.5	Double row of small melanophores	Absent in larvae <10mm; spots present anterior to pectoral fins in larvae >10 mm	Large melanophores medially	Relatively few scattered spots, more anterior than posterior	Large melanophores present, more anterior than posterior
Line of lateral pigment	10-18	Begins anterior to anus	Begins under second dorsal fin	Begins anterior to anus	Begins under second dorsal fin	Begins just anterior to anus
Postanal region						
Length of ventral stripes (based on no. of melanophores)	4-6	Both longer than dorsal stripes	Both shorter than dorsal stripes	Anterior stripe longer than dorsal stripe (<5.3 mm)	Posterior stripe longer than dorsal stripe	Anterior stripe longer than dorsal stripe (<5 mm)
No. of myomeres from vertical end of anus to anterior end of first ventral pigment stripe	4-6	4-6	5-7	1-3 (reaches vent by ~5.3 mm)	4-5	1-3 (reaches vent by ~5.0 mm)
Length at which dorsal pigment forms a continuous line	4-15	~10 mm	~7 mm	~5-6 mm	~13 mm	~13 mm
Length at which ventral pigment forms a continuous line	4-10	~7 mm	~10 mm	~5-6 mm	Never merge	~5-6 mm
On ventral margin of body	10-15	In double row on each side of midline	Pigment on midline and scattered on each side	Single row on each side of midline	Pigment on midline and a single row on each side	Single row on each side of midline anteriorly, single row on midline posteriorly
Morphologic						
Position of vent relative to dorsal fins	15-20	Under second dorsal	Under second dorsal	Under second dorsal	Between first and second dorsal	Between first and second dorsal (ultimately under first dorsal)
Meristic						
No. of rays on superior hypural	>13	5	4	4	4	5

MERISTICS

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	0.98-1.08 mm (1.02 mm)
No. of oil globules	None
Oil globule diameter	
Yolk	Homogeneous, dense
Envelope	Smooth, thick
Hatch size	3-4 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

LARVAE

Preanal length	<50% SL
Length at flexion	10-17 mm SL
Length at transformation	25-35 mm SL

Sequence of fin development

Pigment

- Presence of bars
- Ventral gut with large melanophores (in larvae >20 mm SL, small spots occur in two rows along ventral surface of gut)
- Stripe continuity (~5-6 mm SL)
- Mediolateral pigment begins anterior to anus (~5-6 mm SL)

Diagnostic characters (see Table 22)

- Pigment
 - Large melanophores medially along length of gut
 - Single irregular row of pigment on each side of ventral midline
 - Ventral pigment begins at anus after yolksac absorption
 - Rays on superior hypural = 4
- Distinguished from *Theragra chalcogramma* at yolksac stage by
- Less lateral pigment within bars
 - Posterior bar longer, extending closer to tail
 - Presence of about 2-6 spots in the ventral caudal region
 - More pigment in snout area and on mouth
- Distinguished from *T. chalcogramma* at later stages by
- Generally more pigmented, especially on head and gut

MACROURIDAE

Among the most common of all deep-sea bottom-living fishes, grenadiers are found in all the world's oceans. They have long, tapering bodies and elongate dorsal and anal fins continuous with the tail. A chin barbel is usually present. In the North-east Pacific there are ten species in three genera. Adults have been found in water as shallow as 100 m but are more commonly collected at depths greater than 300 m (Fitch and Lavenberg 1968). Little is known of their early life history. Macrourid eggs are generally 1-2 mm, have a single oil globule, and some species have honeycomb ornamentation on the chorion. Larvae are characterized by an elongate tail, lack of caudal fin, and an elongate pectoral fin peduncle. The transition from larva to juvenile is rapid. The most important morphological change is the loss of the pectoral fin peduncle. Other morphological differences occurring at transformation include small changes in head length, mouth orientation changing from oblique to horizontal, snout becoming more distinct, and the stomach (gut) becoming reduced in prominence (decreasing depth of posterior trunk). The occurrence of juveniles of increasing size at increasing depth suggests an ontogenetic migration of subadults to a benthic existence (Stein 1980a). Some species remain pelagic throughout a prolonged juvenile period (Hubbs and Iwamoto 1977).

Figure A, Fahay and Markle 1984. North Atlantic specimen tentatively identified as *Nezumia*.

Ophidiiformes

The ophidiiforms occupy mostly benthic habitats ranging from the shallow tropics to abyssal depths and subarctic locations. Adults have long tapering bodies, with or without a caudal fin, and long dorsal and anal fins. The order comprises 4 families, 86 genera, and 294 species (J. Nelson 1984). The two suborders are defined according to mode of reproduction: Ophidioidei (Ophidiidae) are oviparous and Bythitoidei (Aphyonidae and Bythitidae) are viviparous (Cohen and Nielsen 1978). Ophidiiform eggs of oviparous forms are pelagic, may have one oil globule, and are spherical or ellipsoidal (Gordon et al. 1984). Larvae are not well known; of the eight species found in the study area only two larval series have been identified and are presented here. A third series of an unidentified ophidiid has been tentatively identified as *Spectrunculus grandis*.

Families in study area: **Ophidiidae**
Aphyonidae
Bythitidae

OPHIDIIDAE

Fishes of this group are found primarily in tropical and temperate waters, although a few occur in subarctic locations. In the northeastern Pacific there are six species within five genera in the family. Larvae are known only for *Chilara taylori*, but a second series has been tentatively identified as *Spectrunculus grandis*. These larvae occur in samples collected off northern California, Oregon, and Washington. Since meristic characters, especially vertebral counts, are unavailable for several species in the area, only a tentative identification can be made. Available meristics, however, match those of *Spectrunculus grandis*. These larvae resemble those of the pleuronectid, *Embassichthys bathybius*, and have been routinely mixed with them in samples. They can be distinguished from *E. bathybius* (p. 580) larvae by number of myomeres (>75 vs. 65), less finfold pigment, and a less pronounced loop in the gut.

Lophiiformes

The order Lophiiformes includes some of the most unusual fishes known. Adults exhibit several forms: Dorsoventrally flattened and ventrally compressed forms found in shallow-water benthic habitat, and globose, flabby-bodied forms found at meso- and bathypelagic depths. Worldwide there are 18 families, 63 genera, and 262 species (Pietsch 1984). All families are characterized by having a luring apparatus (illicium) bearing a terminal bait (esca) originating from three modified anterior dorsal spines and a narrow tube-like gill opening located near the pectoral fin. Extreme sexual dimorphism is common among the fishes within the suborder Ceratioidei. Males are one-third the size of females or smaller and sometimes are permanently attached (parasitic) to them. Eggs of most lophiiforms are spawned in gelatinous “veils” which may be up to 1.5 m wide and 12 m long (Pietsch 1984). Several species have eggs attached to the adult (Pietsch and Grobecker 1987). Larvae are pelagic and many have large heads and an envelope of highly inflated skin. Neither eggs nor larvae have been collected in the study area.

Families in study area: **Ceratiidae**
Oneirodidae

CERATIOIDEI

The suborder Ceratioidei is represented within the study area by members of the families Oneirodidae and Ceratiidae. Ceratioids differ from other members of the Lophiiformes in being meso- and bathypelagic, lacking pelvic fins (except larval Caulophrynidae), and in having extreme sexual dimorphism.

Oneirodidae

Found worldwide, oneirodids (dreamers) are represented by five species within three genera (*Oneirodes*, *Chaenophryne*, and *Bertella*) in the Northeast Pacific. Reproduction is accomplished by facultative or non-parasitic attachment of the male onto the body of the female (Pietsch 1976). Eggs and larvae are pelagic. Eggs are probably released in gelatinous veils which might break up in plankton nets. Eggs are presumably small, generally 0.5-0.8 mm, and hatching occurs between 2.5 and 3.5 mm SL (Bertelsen 1984). Larvae have a transparent envelope of gelatin, under colorless skin, which may serve as an aid to flotation (Idyll 1964, Pietsch 1984).

According to Bertelsen (1984), larval characters for oneirodids include the following:

- Presence in larval males of a rudiment of illical bone
- Moderately elongate body shape (body depth up to 80-90% in most ceratioids but less pronounced in oneirodids)
- Larvae surrounded by inflated transparent skin (similar to other ceratioids)
- Head length usually about 45% SL
- Pigment: Ceratioids possess four main pigment areas (peritoneal, dorsal, caudal, and opercular). In oneirodids, the opercular pigment is dense and occurs in different patterns

At metamorphosis (usually between 8 and 10 mm SL), larvae descend into deeper waters.

Ceratiidae

Recently, two ceratiids (seadevils) have been identified from the Bering Sea, *Ceratius holboelli* and *Ceratius* sp. (Pietsch 1986). Larval ceratiids are distinguished from other ceratioid families in having the following combination of characters (Pietsch 1986):

- Body “hump-backed,” mouth subvertical
- Female with caruncles on dorsal surface of trunk
- 4-5 dorsal fin rays, 4 anal fin rays
- Pectoral fins not reaching beyond dorsal and anal fins
- Pelvic fins absent

Figures A–E, Bertelsen 1951 (North Atlantic specimens from the *O. eschrichti* group).

Gobiesociformes

The gobiesociforms (clingfishes) are mostly small, inshore bottom-dwelling species occurring in tropical and temperate seas. Noted primarily for having the pelvic fins modified into a sucking disc, the order has 2 families, 36 genera, and 114 species (J. Nelson 1984). All but one genus and four species are members of Gobiesocidae. Eggs are demersal, attached to substrate or kelp, ovate to ellipsoidal, and 0.7-1.9 mm. Oil globules (1-100) coalesce to one during development (Allen 1984). Larvae are well developed at hatching and may have a fully formed pelvic disc at this time (Marliave 1975a). Most are heavily pigmented and have long guts (50-70% SL) (Allen 1984).

Family in study area: **Gobiesocidae**

Length at transformation	
Sequence of fin development	
Pigment (based on figure only)	<ul style="list-style-type: none"> • Lateral melanophores (40-50) • No postanal ventral melanophores • No hypural pigment

Diagnostic characters

- Pelvic disc at hatching
- Number of myomeres (35-36)

Note: Marliave (1975a) reared *Rimicola muscarum* in the laboratory. Eggs (1.3 mm in diameter) had a single oil globule, and late-stage embryos developed a pelvic disc. Hatching occurred when embryos reached 4.0 mm SL. He described them as identical to *Gobiesox maeandricus* larvae except that they were markedly smaller, without nasal pigment, and with the pelvic disc at hatching. According to Marliave (Vancouver Public Aquarium, P.O. Box 3232, Vancouver, B.C., Canada V6B 3X8, pers. commun., 16 Oct. 1986), *R. muscarum* probably lacks a pelagic stage and the specimen illustrated here from Allen (1979) is misidentified.

Atherinomorpha: Beloniformes
Atheriniformes

The Beloniformes and Atheriniformes together comprise a group of fishes found in freshwater and marine habitats within tropical and temperate areas. The Beloniformes (not always accorded ordinal status [J. Nelson 1984]), consists of 5 families, 37 genera, and 180 species (Collette et al. 1984a). Marine forms of this order are mostly epipelagic, the best known being exocoetids, or flying fish. There are 6 families (White et al. 1984), 49 genera, and 235 species of atheriniforms (J. Nelson 1984). The two orders belong to the superorder Atherinomorpha and share the development of large demersal eggs with filaments and oil globules that coalesce at the vegetal pole (Collette 1984). Filaments may be short or long, grouped or evenly scattered, and adhesive or non-adhesive. Beloniform larvae are well formed at hatching and many have a preanal finfold and beak-like jaws (Collette et al. 1984a). Atheriniform larvae have direct development (i.e., no specialized larval or juvenile stages), a preanal finfold, and a single row of melanophores on the dorsal midline (White et al. 1984).

Families in study area: **Scomberesocidae**
Atherinidae

EARLY LIFE HISTORY DESCRIPTION^c**EGGS**

Diameter	1.9-2.5 mm ^b
No. of oil globules	Many (23-44) which coalesce to one or few
Oil globule diameter	0.4-0.6 mm (consolidated)
Yolk	Yellow-orange, granular
Envelope	13-19 filaments scattered on surface
Hatch size	7.5-8.6 mm SL; yolk absorbed by 10 mm SL
Incubation time/temp.	17-19 d/12-16°C
Pigment	<ul style="list-style-type: none"> • Dorsal spots along nape

Diagnostic characters

- Narrow perivitelline space
- 1-2 cm filaments

LARVAE

Preanal length	<50% SL
Length at flexion	8.8 to ≤11.5 mm SL
Length at transformation	18.1-19.5 mm SL
Sequence of fin development	Caudal, pectorals, anal rays and 2nd dorsal, pelvics, 1st dorsal and anal spines

Pigment

- Dorsal midline from snout to caudal peduncle, sometimes with a break in nape area
- Mediolateral usually begins posterior to gut during preflexion stage

Diagnostic charactersDistinguished from *Atherinopsis affinis* by

- First 5-6 postanal myomeres always lack ventral pigment through the larval and early juvenile stages
- Lack of ventral midline melanophores until midflexion
- Mediolateral pigment originates further posterior

Figure A, White et al. 1984; B–E (C, ventral view), Watson and McGowen, unpubl.

Lampriformes

Fishes of the order Lampriformes are extremely diverse. Occupying meso- and epipelagic habitats, some are deep-bodied while others are long and ribbon-like. Extreme specialization and unique body shapes have caused conflicting proposals for evolutionary relationships within the order (Olney 1984). According to Olney (1984), there are 7 families, 12 genera, and 21 families worldwide (not found in polar seas). Lampriforms share the unique arrangement of protrusible premaxilla and maxilla, or specializations thereof. Early-life-history information is available for only four genera. Eggs are large (1.7-4.0 mm) with thick resilient chorions, pelagic, and may be shaded with amber, pink, or red hues. Advanced stages of eggs of some forms are easily recognized due to precocious development of anterior dorsal and pelvic rays and distinctive pigment patterns. Newly hatched lampriforms are identified by their well-developed protrusible jaws and elongate anterior dorsal and pelvic fin elements which are often ornamented with highly pigmented serial or terminal swellings (Olney 1984).

Families in study area: **Lampridae**
Trachipteridae

Figure A, Matarese and Sandknop 1984; B–C, NWAFC originals (B. Vinter).

Beryciformes

Fishes of the order Beryciformes are cosmopolitan in distribution. The composition of the order is subject to much variation, but according to Keene and Tighe (1984), it consists of 16 families, 42 genera, and 155 species. Although several characters define the beryciforms (e.g., a high number of pelvic and caudal fin rays and the presence of dorsal, anal, and pelvic fin spines), none are unique to the order. No information is available on eggs, and other early-life-history stages are known for only six families. In the Northeast Pacific, larvae are known for only two families, Anoplogastridae and Melamphaidae. Anoplogastrids have large heads with short deep bodies, and well-developed preopercular, rostral, and cranial spines. Larvae of the best known family, Melamphaidae, are longer-bodied and more slender with spination generally restricted to the preopercle.

A summary of meristic characters is provided for members of the suborder Cetomimoidei (Barbourisiidae, Cetomimidae, Rondeletiidae), as larvae are unknown.

Families in study area: **Anoplogastridae**
Melamphaidae
Barbourisiidae
Cetomimidae
Rondeletiidae

MELAMPHAIDAE

Melamphoids, or bigscales, are small (15 cm), darkly colored, bathypelagic fish found in most oceans. They are distinguished by exceptionally thin skull bones, sometimes with ridges or crests. They are represented in the study area by five species within four genera: *Melamphaes*, *Poromitra*, *Scopeloberyx*, and *Scopelogadus*. A complete descriptive series is known only for *Melamphaes lugubris*. Generally, small melamphaid larvae (2-10 mm) are relatively elongate and slender as compared with later stages, and possess early and rapidly developing pelvic fins which are long and darkly pigmented. *Melamphaes*, *Scopeloberyx*, and *Scopelogadus* larvae usually have two spots near the posterior end of the dorsal and anal fin margin; with development these spots spread both anteriorly and posteriorly along the dorsal and ventral midlines (Keene and Tighe 1984). Other pigment occurs on the cranium, peritoneum, and along the caudal peduncle. Although usually damaged, the second or third dorsal fin ray is elongate in larvae of these three genera. Larger larvae (5-10 to 20 mm) can generally be distinguished by body shape, presence of preopercular spines (e.g., *Poromitra*), and meristic characters. The following generic meristic characters are based on Ebeling (1962) and E.H. Ahlstrom notes, in part.

Genus	Vertebrae	Fins			
		Dorsal	Anal	Pectoral	Pelvic
<i>Melamphaes</i>	27-31	III, 13-16	I,7-9	14-17	I,7

CETOMIMOIDEI

Fishes of the suborder Cetomimoidei are bathypelagic with whale-shaped bodies, large mouths, highly distensible stomachs, and luminous tissue on the body. Eyes may be reduced or rudimentary. Whalefishes are divided into three families: Cetomimidae, Rondeletiidae, and Barbourisiidae. Worldwide in distribution, the suborder consists of 8 genera and 18 species. Of these, five species in five genera have been collected in the northeastern Pacific. Adults are taken by deep tows generally in excess of 400 m, and then only rarely. No information on life history, eggs, or larvae is available (Keene and Tighe 1984).

Zeiformes

The zeiformes occur in tropic and temperate areas of all oceans, in benthic and pelagic habitats from shallow to deep-water areas; little else is known of the life history of most fish in this group. Adults are generally deep-bodied with large eyes, greatly distensible jaws, and dorsal, anal and/or pelvic fin spines. The order is loosely organized according to a number of characters, none of which are unique. Presently, there are 6 families, 21 genera, and about 36 species throughout their distribution (J. Nelson 1984). The order is represented in the study area by one taxon, *Alloctytus* sp., a member of the Oreosomatidae. Eggs of only three species are known. Sizes range from 1.0 to 2.25 mm in diameter; all have a smooth chorion, homogeneous yolk, and a single oil globule (Tighe and Keene 1984). Larvae are generally deep-bodied and may be heavily pigmented. Forms exhibit a variety of armaments including serrated cranial ridges and spines, preopercular spines, and hardened cones or scaly knobs.

Family in study area: **Oreosomatidae**

Diagnostic characters - Family

- Limited data on prejuveniles only; pelagic prejuveniles are oval in outline and possess a leathery skin with distinct hardened cones or scaly knobs laterally and ventrally

^a *Allocyttus folletti* and *A. verrucosus* may occur in the study area, but identification to species is not possible. Kobayashi et al. (1968) suggested *A. folletti* should be a synonym of *A. verrucosus*.

^b Early-life-history stages of *Allocyttus* spp. are unknown. An illustration of a prejuvenile of *Oreosoma atlanticum* is presented for comparison only. A photograph of an *Allocyttus verrucosus* juvenile (95 mm TL) is presented in Kobayashi et al. (1968).

Figure A, Abe and Kaji 1972 (Tasman Sea specimen).

Gasterosteiformes

The order Gasterosteiformes is made up of small, cryptically colored fish found in freshwater or marine habitats in tropical and temperate areas. Most species have small mouths at the end of tubular snouts and dermal plates covering the body. Historically divided into two or three orders, the group, as supported by Pietsch (1978) and Fritzsche (1984), contains 10 families with well over 200 species. Eggs are broadcast or deposited in nests or on algae, or for syngnathids, in male brood pouches. Eggs of families other than Syngnathidae are 1.5-2.1 mm in diameter, may have one or more oil globules, and have thick chorions. Most gasterosteiform larvae hatching from externally incubated eggs (except gasterosteids) have the same distinctive characters (i.e., elongate snout and small mouth, dermal plates) as the adults. Although adult gasterosteids are sometimes collected in plankton samples, early-life-history stages are unlikely to occur and are not treated here.

Families in study area: **Aulorhynchidae**
Gasterosteidae
Syngnathidae

Scorpaeniformes

Most scorpaeniforms are bottom-oriented and have large heads, large rounded pectoral fins, rounded caudal fins, and many have head spines or bony plates (or combinations thereof). One character unites the group: a bony suborbital stay extending from the third suborbital bone to the opercle. Within the Scorpaeniformes, there are 20 families, 269 genera, and about 1160 species (J. Nelson 1984). The order is usually divided into four suborders: Scorpaenoidei, Anoplopomatoidei, Hexagrammoidei, and Cottoidei. Although members of the order are distributed worldwide, more than 250 species occur in the North Pacific Ocean and Bering Sea of which 190 are endemic.

Reproduction is oviparous except in *Sebastes* where eggs are internally fertilized and live feeding young are extruded. Larvae are extremely diverse. Head spines are common in larval scorpaenoids and cottoids.

Families in study area: **Scorpaenidae**
Anoplopomatidae
Hexagrammidae
Cottidae
Agonidae
Cyclopteridae

SCORPAENIDAE

Scorpaenidae

In the study area this speciose family consists of *Sebastes*, with about 40 species, and *Sebastolobus* with 3 species. The larvae can be identified to genus, but identification is presently possible for only a few of the species of *Sebastes*. Information is included here which will aid in identifying species for which early-life-history series are known, and also characters are presented which may prove useful in identifying species whose larvae are not yet known. Full text pages are provided for those species for which an illustration is available of a postflexion larva and at least one other stage. Species with illustrations of only an extrusion larva or pelagic juvenile are treated in the comparative sections. For *Sebastes* species accounts, a section on head spines has been substituted for the egg section, and counts of lateral line pores and total gill rakers have been added to the meristic section.

Sebastinae

Among the 70 or so species of *Sebastes* in the Northeast Pacific, 40 species are known to occur in the study area (Table 29). Meristic information on the following pages has been updated from recent sources (Chen 1986; Laroche, in prep.). *Sebastes* are ovoviviparous (or viviparous¹) and give birth to live young which are similar in stage of development to first-feeding larvae of oviparous scorpaenids. Eggs, generally between 0.75 and 1.9 mm diameter, are retained in the lumen of the ovary after ovulation and internal fertilization. Eggs possess a homogeneous yolk, narrow perivitelline space, fragile smooth chorion, and one to many oil globules. Hatching precedes extrusion with newborn larvae, 3.8-7.5 mm SL, having already utilized most of their yolk.

Newly extruded larvae have functional eyes, jaws, and pectoral fins. Notochord flexion occurs at about 6-12 mm SL and transformation (acquisition of adult complement of fin rays) occurs at about 15-25 mm SL. Many species have a distinct pelagic juvenile stage that may last until about 60 mm SL. Preflexion larvae have relatively slender bodies and compact guts (13-23% SL). Snout-to-anus length may increase from 40-50% SL to >60% SL in some species during the larval period. Preflexion larvae usually have pigment over the gut and a series of postanal ventral melanophores. Some species may have pigment along the dorsal midline which develops gradually. Other pigment may occur on the brain, jaws, opercle, fins (especially pectorals), and caudal peduncle.

A prominent feature in *Sebastes* larvae is head spination. Pterotic, parietal, and preopercular spines form before larvae undergo flexion, and other spines appear gradually thereafter. The full complement of head spines generally develops during the larval period, and some spines that develop in the larval period (e.g., pterotic, anterior preopercles, and lower posttemporal, and others in some) are overgrown during the juvenile stage (Washington et al. 1984b).

Larval series of 16 species of *Sebastes* occurring in our study area are known. Extrusion or yolk-exhaustion larvae have been illustrated for 32 species, and pelagic juveniles have been illustrated for 33 species. Although *Sebastes* larvae are often abundant in plankton samples from the Northeast Pacific in winter and spring, the specific identity of most cannot presently be determined.

Sebastolobinae

Sebastolobus is represented by three species in the study area. Eggs are extruded in bilobed gelatinous masses which float at the surface. The eggs are slightly elliptical and have homogeneous yolk, a narrow perivitelline space, and a smooth chorion. A single oil globule (0.18-0.20 mm diameter) is present (Pearcy 1962, Moser 1974).

Besides differences in meristic characters, *Sebastolobus* larvae can be distinguished from those of *Sebastes* in that preflexion larvae have a postanal band of pigment instead of the ventral and possibly dorsal midline melanophores in *Sebastes*. A parietal ridge develops in *Sebastolobus* and terminates in a double spine, the parietal and nuchal. In *Sebastes* the parietal spine develops singly, usually with a smaller nuchal spine immediately posterior to it.

¹Boehlert and Yoklavich (1984) demonstrated that in *Sebastes melanops* the embryos receive some nutrition from the ovarian fluid during gestation.

Table 29

Distribution, parturition season, and meristic characters of genus *Sebastes*. Range of counts followed by mode in parentheses. All have modal counts of 13 dorsal spines (except *S. polyspinis* with 14^a) and 3 anal spines (Chen 1986).

Head spines

There are differences in terminology for *Sebastes* head spines between the two major sources of early-life-history descriptions (i.e., Richardson and Laroche 1979, Moser and Ahlstrom 1978). Most of the differences are semantic; however, the numbering of anterior preopercular spines is a substantive difference (Table 30). Among the species studied to date, posterior preopercular spine 1 has not had an anterior spine associated with it. Therefore, Richardson and Laroche (1979) gave the number 1 to the anterior preopercular spine associated with the second posterior preopercular spine. Moser and Ahlstrom (1978) gave the same numbers to the anterior and posterior preopercular spines. Thus the same anterior preopercular spine is numbered one less by Richardson and Laroche (1979) than it is by Moser and Ahlstrom (1978). Succeeding descriptions by these and other authors perpetuate these differences (e.g., Washington et al. 1984b). Here we use the system of Moser and Ahlstrom (1978).

There are also differences between the *Sebastes* head spine terminology used for adults and that used for larvae (Table 30). This situation resulted from the difficulty of determining spine/bone associations by external examination of adults and is complicated by the overgrowth of some spines during development (Richardson and Laroche 1979). The major points of confusion are that the supracleithral of larvae is called the upper posttemporal spine of adults, and the cleithral spine of larvae is called the supracleithral spine of adults. Head spine patterns which may help identify adult *Sebastes* are listed in Table 31.

Table 30
Head spine terminology in *Sebastes*, listed by sequence in which the spines develop in *S. melanostomus* (Moser and Ahlstrom 1978). Names used by Richardson and Laroche (1979) are listed only when they differ from those used by Moser and Ahlstrom (1978).

Abbreviation	Moser and Ahlstrom (1978)	Richardson and Laroche (1979)	Bone of origin	Adult spine
PA	Parietal		Parietal	Parietal
NU	Nuchal		Parietal	Nuchal
PSO	Postocular		Frontal	Postocular
PT	Pterotic		Pterotic	(Overgrown)
LPST	Lower posttemporal	Inferior posttemporal	Posttemporal	(Overgrown)
UOP	Upper opercular	Superior opercular	Opercle	Opercular
UIO-1	1st upper infraorbital	Superior infraorbital series, 1st	Infraorbital 1	(Overgrown)
LIO-1	1st lower infraorbital	Inferior infraorbital series, 1st	Infraorbital 1	Lachrymal projection (suborbital spine)
APO-2	2nd anterior preopercular	Anterior preopercular series, 1st	Preopercle	(Overgrown)
PPO-2	2nd posterior preopercular	Posterior preopercular series, 2nd	Preopercle	Preopercular
APO-3	3rd anterior preopercular	Anterior preopercular series, 2nd	Preopercle	(Overgrown)
PPO-3	3rd posterior preopercular	Posterior preopercular series, 3rd	Preopercle	Preopercular
APO-4	4th anterior preopercular	Anterior preopercular series, 3rd	Preopercle	(Overgrown)
PPO-4	4th posterior preopercular	Posterior preopercular series, 4th	Preopercle	Preopercular
PPO-1	1st posterior preopercular	Posterior preopercular series, 1st	Preopercle	Preopercular
PPO-5	5th posterior preopercular	Posterior preopercular series, 5th	Preopercle	Preopercular
UIO-4	4th upper infraorbital	Superior infraorbital series, 4th	Infraorbital 3	(Overgrown)
SC	Supracleithral		Supracleithrum	Cleithral
LIO-2	2nd lower infraorbital	Inferior infraorbital series, 2nd	Infraorbital 1	Lachrymal projection (suborbital spine)
LIO-3		Inferior infraorbital series, 3rd	Infraorbital 1	(Overgrown)
LOP	Lower opercular	Inferior opercular	Opercle	Opercular
UIO-2	2nd upper infraorbital	Superior infraorbital series, 2nd	Infraorbital 1	(Overgrown)
UPST	Upper posttemporal	Superior posttemporal	Posttemporal	Supracleithral
SPO	Supraocular		Frontal	Supraocular
UIO-3	3rd upper infraorbital	Superior infraorbital series, 3rd	Infraorbital 2	(Overgrown)
NA	Nasal		Nasal	Nasal
PRO	Preocular		Lateral ethmoid (prefrontal)	Preocular
CL	Cleithral		Cleithrum	(Overgrown)
IOP	Interopercular		Interopercular (interopercle)	Gill cover spine
TM	Tympanic		Frontal	Tympanic
SOP	Subopercular		Subopercular (subopercle)	Gill cover spine
CO	Coronal		Frontal	Coronal

Positions and abbreviations of larval head spines in larval *Sebastes*. Based on a 16.0-mm stained larva of *Sebastes melanostomus* augmented to show the position of the coronal (CO) and 3rd lower infraorbital (LIO-3) spines. From Moser and Ahlstrom (1978) and Laroche (in prep.).

Table 31
Presence and absence of head spines which are diagnostic for adults of members of the genus *Sebastes*
(+ indicates presence, 0 indicates absence, blank indicates unknown character state).

Extrusion or Yolk-Exhaustion Larvae

Various authors have illustrated and described larvae which have been extruded from pregnant female *Sebastes*. In some cases, the larvae have been maintained in seawater for several days after extrusion, and in a few cases (e.g., Stahl-Johnson 1985, Moser and Butler 1987) the larvae were fed and reared. With handling, pregnant *Sebastes* will release larvae that are not full-term, and such larvae may be represented in some illustrations. Furthermore, some illustrations were drawn by adding observed pigmentation for a particular species to a general outline of an extrusion *Sebastes* larva (c.f. Westrheim et al. 1968a). The generalized outline used by Westrheim et al. (e.g., 1968a) and DeLacy et al. (1964) lacked pectoral fins, apparently the result of an oversight. Several illustrations of extrusion larvae have been published for some species, and there are notable differences among some of these illustrations. One of the illustrations of an extrusion larva purported to be *Sebastes zacentrus* by Harling et al. (1971) was obviously misidentified, as discussed by Laroche and Richardson (1981). With these problems in mind, pages 273-280 present all of the published, and some previously unpublished, illustrations of extrusion larvae of *Sebastes* spp. which occur in the study area, not so much for use in species identifications but as reference for further research.

Sebastes Pelagic Juveniles

The following six pages present illustrations of pelagic juveniles of 33 of the 40 species of *Sebastes* occurring in the study area. Pelagic juveniles of the remaining species are unknown or have not yet been illustrated. Illustrations are grouped to form a pictorial key based primarily on pigment characters of the juveniles as derived from Laroche (in prep.). Species are grouped on the pages according to predominant pigment characters; within these groups, species are separated according to other pigment characters. Several species possess identical states for these characters. Identification of these will require use of additional characters such as meristics, body shape, head spination, time and location of collection, and other pigment characters. These characters should also be checked on fish separated based on the pictorial key to verify their identity. Variation in pigment can be expected due to size and other differences in specimens of a species. Also, pigment characters of species for which pelagic juveniles are unknown may closely resemble those species illustrated here, which would lead to misidentification unless other characters were examined.

PELAGIC JUVENILES
Black pigment blotch at posterior of spinous dorsal fin

Diffuse body pigment	Pectoral fin base unpigmented	Anal fin unpigmented	Lateral midline pigmented	<p>A <i>S. melanops</i></p>  <p>45.3 mm SL</p>
			Ventral caudal peduncle pigmented	<p>B <i>S. flavidus</i></p>  <p>42.0 mm SL</p>

Hatch size	4.7-6.7 mm SL
Preanal length	<50% SL
Length at flexion	Between 7.4 and 9.0 mm SL

Length at transformation

Sequence of fin development	Caudal and pectorals, pelvics, dorsal and anal
-----------------------------	--

Pigment^d

- Mostly on dorsal head, with development covering entire head
- Nape
- Gut: Dorsal and ventrolateral surface, increasing laterally with development
- Dorsal and ventral midline melanophores begin posterior to anus; with development, dorsal melanophores extend to nape
- Increase in lateral pigment on posterior half of body and to hypural region
- Pectoral fins

Diagnostic characters

- Distinguished from *S. caurinus* (p. 296) by
- Dorsal midline melanophores postanally at birth, gradually spread forward to nape
 - More pigment on opercular than in *S. caurinus*

PELAGIC JUVENILES

- Diffuse body pigment
- Opercular pigment blotch present
- Lateral midline pigmented

Unpigmented area dorsally,
myomeres 1–8

EARLY LIFE HISTORY DESCRIPTION**LARVAE**

Hatch size	4.4 mm SL
Preanal length	~44% increasing with development to 64% SL
Length at flexion	6.5-8.6 mm SL
Length at transformation	13 mm SL
Sequence of fin development	Caudal; pectorals; pelvics, dorsal, and anal
Pigment	<ul style="list-style-type: none"> • Head: Dorsal spots spreading with development to opercle then to entire head • Snout and jaws pigmented • Gut: Posterior pigment increasing dorsolaterally with development • Postanal body: Dorsal and ventral midline over body (between postanal myomeres 4 and 15); lateral pigment increases with development to form a band • Pectoral fin first, other fins with development

Diagnostic characters

- Morphology: Snout-to-anus length greater than in other species studied
- Pigment: Snout, postanal band

PELAGIC JUVENILES^c

- Low total gill raker count (24-28) and lateral line pore count (28-31) are diagnostic for the species
- Body pigment faintly banded with unpigmented caudal peduncle
- Pectoral rays heavily pigmented medially

^aWyllie Echeverria 1987

^bAccording to Moser et al. (1985), the preocular spine develops by 10.5 mm SL but is not visible on their 13.5-mm SL specimen shown here.

^cLargest pelagic juvenile collected is 34.4 mm SL.

EARLY LIFE HISTORY DESCRIPTION**LARVAE**

Hatch size	5.3 mm SL
Preanal length	41% SL increasing with development to 49% SL
Length at flexion	Between 7.5 and 9.5 mm SL

Length at transformation

Sequence of fin development	Caudal and pectorals, pelvics, dorsal and anal
-----------------------------	--

Pigment

- Head: Dorsal and nape spreading, with development, to entire head
- Gut: Dorsal and ventrolateral surface, increasing laterally with development
- Dorsal midline melanophores extend from head to just anterior to tail with no break over gut
- Ventral midline melanophores, with development increasing ventrolaterally and in hypural region

Diagnostic characters

- See notes on *S. auriculatus* (p. 290) about reared specimens
- Distinguished from *S. auriculatus* by
- Until midflexion, more dorsal midline pigment anterior to anus
- Less pigment in the opercular region (flexion and postflexion)

PELAGIC JUVENILES

- Four pigment bands on body
- Fins pigmented

EARLY LIFE HISTORY DESCRIPTION**LARVAE**

Hatch size	5.7 mm SL
Preanal length	54-65% SL
Length at flexion	8.0-9.3 mm SL
Length at transformation	16-21 mm SL ^e
Sequence of fin development	Caudal and pectorals, pelvics, dorsal and anal

Pigment

- Extrusion larvae: Series along ventral body
- Pigmented pectorals and pelvics
- Heavy nape and top of head
- No dorsal midline
- ~11 ventral midline melanophores reducing to ~4 on caudal peduncle
- Spinous dorsal fin
- Tip of lower jaw

Diagnostic characters

- Heavy nape and paired fin pigment
- Pigment on spinous dorsal fin

PELAGIC JUVENILES

- Five pigment bands on body, four extending onto dorsal fin
- Paired fins heavily pigmented

^aHart 1973^bHitz 1962^cPhillips 1964^dWyllie Echeverria 1987^eJuveniles become benthic at 40-60 mm SL.

EARLY LIFE HISTORY DESCRIPTION

LARVAE

Hatch size	5.4 mm SL
Preanal length	36%, with development 54% SL
Length at flexion	8-10 mm SL
Length at transformation	~27-30 mm SL ^e
Sequence of fin development	Caudal and pectorals, pelvics, dorsal and anal

Pigment

- Brain (dorsal head on crown)
- Pigment over dorsolateral surface of gut
- Dorsal and ventral postanal midline (see illustrations)

Diagnostic characters

- Most slender *Sebastes* sp. larvae described to date (body depth <25% SL)
- Large larvae (5.4 mm SL at hatching, 8-10 mm SL at flexion)
- Opposing dorsal and ventral postanal midline pigment
- Anterior placement of anus in juveniles/adults
- Large gap between anus and origin of anal fin

PELAGIC JUVENILES

- Elongate shape, large gap between anus and origin of anal fin
- Body pigment diffuse, but myosepta pattern evident

^aPhillips 1964

^bWestrheim 1975

EARLY LIFE HISTORY DESCRIPTION

LARVAE

Hatch size	4.5 mm SL
Preanal length	37% SL increasing with development to 62% SL
Length at flexion	6.2-7.2 mm SL
Length at transformation	~16 mm SL ^c
Sequence of fin development	Caudal and pectorals, pelvics, dorsal and anal

Pigment

- Preflexion larvae
 - Single row postanal ventral midline (~8 spots)
 - Brain
 - Lower jaw, streak along upper jaw
 - Dorsolaterally on gut
 - Pectoral fin
- Flexion larvae: Opercle blotch and upper jaw streak
- Postflexion and pelagic juveniles: Anterior bar; with development, two additional bars form, under second dorsal and on caudal peduncle

Diagnostic characters

- Pigment
 - Jaw, opercle blotch, postanal bars
 - Blades of paired fins heavily pigmented
 - Band of pigment on body centered at about dorsal spine 5-7
- Head spination (see p. 271)
 - Large serrate parietal spine
 - Large weakly serrate preopercle angle spine
- Deep bodied (>35% SL)

PELAGIC JUVENILES

- Banded body pigment extends onto dorsal and anal fins
- Pectoral fin, but not base, pigmented

^aMoser and Ahlstrom 1978

^bWyllie Echeverria 1987

^cLargest pelagic juvenile collected is 46.2 mm SL; smallest demersal juvenile collected is 36.0 mm SL.

development

Pigment

- Extrusion larvae: Short series midway along ventral body
- Postflexion larvae >12.3 mm SL
 - Dorsolateral patch under spinous dorsal
 - Along dorsal and anal fin ray bases
 - Series along ventral midline toward caudal, becoming internal
 - Along hypural margin

Diagnostic characters

PELAGIC JUVENILES

- Body and head pigment diffuse, heavy
- Pigment blotch on last few dorsal fin spines
- Paired fins pigmented

EARLY LIFE HISTORY DESCRIPTION**LARVAE**

Hatch size	3.6-4.0 mm SL
Preanal length	59-64% SL
Length at flexion	<7.8-8.8 mm SL
Length at transformation	12.8-18.4 mm SL ^f
Sequence of fin development	Caudal and pectorals, pelvics, dorsal and anal

Pigment

- Initially: Lower jaw, ventral surface of gut and posterior gut, short dorsal and ventral midline series at $\sim 3/4$ BL between myomeres 18 and 24
- Short dorsal and ventral midline series on caudal peduncle
- Lightly pigmented paired fins
- Head: Dorsal surface; with development, patch also on upper part of opercle
- Paired fins have large melanophores on blades

Diagnostic characters

- Pigment: Opercular spot, spots on nape
- Morphology: Deep bodied ($\sim 40\%$ SL)
- Spines: Large serrate parietal and third posterior preopercular spine

PELAGIC JUVENILES

- Body pigment banded, mainly above lateral midline
- Pigment blotch on last few dorsal fin spines, little pigment on rest of fins

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	2.05-2.10 mm
No. of oil globules	None
Yolk	Homogeneous
Envelope	Smooth, unsculptured
Hatch size	6 mm SL
Incubation time/temp.	
Pigment	• Unpigmented embryo

Diagnostic characters

- Narrow perivitelline space
- Unpigmented embryo with high myomere count and long gut
- No oil globule
- Large size (2.05-2.10 mm)

LARVAE

Preanal length	50-60% SL
Length at flexion	~12.0 mm SL
Length at transformation	
Sequence of fin development	Caudal, pectorals, 2nd dorsal (rays) and anal, 1st dorsal (spines), pelvics
Pigment	• Initially unpigmented • Preflexion larvae develop dorsal and ventral midline pigment • Flexion and later larvae are heavily and uniformly pigmented

Diagnostic characters (see Table 3)

- Slender, heavily pigmented larvae (flexion)
- Long preanal length (50-60% SL)
- >15 mm SL: long pigmented pectoral fins
- Separate dorsal fins (larger larvae)

Larvae of *Erilepis zonifer* (skilfish), an anoplopomatid from the study area, are unknown. The following meristics distinguish them from *A. fimbria*.

Total vertebrae	45-46
Dorsal fin rays	XII-XVI, 15-19
Pectoral fin rays	16-19
Anal fin rays	III, 11-14

Figures A–D, Kendall and Matarese 1987; E–F, Ahlstrom and Stevens 1976.

Hexagrammidae

The greenlings, endemic to the North Pacific Ocean, are composed in our area of nine species in five genera. Most adult greenlings are demersal and occur nearshore; however, larvae commonly occur off the continental shelf. Eggs are demersal and are usually guarded in nests. Development from hatching to juvenile is direct without any marked transformation. An epipelagic juvenile stage occurs in most species. Larvae are heavily pigmented with scattered melanophores over most of the body, especially dorsally. Characters that will distinguish hexagrammids from other heavily pigmented larvae are presented in Table 3. Identification is accomplished using a combination of pigment and meristic characters along with geographic occurrence. *Oxylebius pictus* and *Zaniolepis* spp. larvae have lower vertebral counts, larger pectoral fins with heavier pigment, and differ from other genera in a number of morphological features (e.g., larger heads, longer preanal length, and deeper bodies). *Ophiodon elongatus* larvae can be separated by the presence of a pointed snout and a large terminal mouth. *Pleurogrammus monopterygius* larvae lack pigment on the snout which serves to distinguish them from larvae of *Hexagrammos* spp. Differences among the larvae of the various species of *Hexagrammos* spp. are discussed in Tables 34-35 and illustrated on page 351.

Table 32
Meristic characters of Northeast Pacific hexagrammids. For all species the normal count for branchiostegal rays is 6 and for pelvic fin rays is 1,5 (Kendall and Vinter 1984).

*Anal spines are very weak in *Pleurogrammus* and *Hexagrammos*, therefore only total anal fin elements are given for these taxa. Counts for anal spines in specific taxa are given on the individual text pages.

Table 33
Larval characters that allow distinction between *Oxylebius pictus* and *Zaniolepis* spp. (Kendall and Vinter 1984).

	<i>Oxylebius pictus</i>	<i>Zaniolepis</i> spp.
3-7 mm SL		
Presence of pigment		
On isthmus	No	Yes
Laterally above gut	Less	More
On ventral midline of trunk	More	Less
On tip of snout and onto tip of palate	No	Yes
On internal surface of pectoral fin base	Yes	No
On lower lip	No	Sometimes
Morphology		
Eye size	Smaller (<20% head length)	Larger (>30% head length)
Preanal finfold (5 to 8 mm)	No	Yes
Pectoral fin length	Reaches anus by 8.0 mm	Reaches anus by 5.5 mm
Notochord flexion	7-9 mm	5-7 mm
Dorsal indentation on eye	No	Yes
>7 mm SL		
Spiny scales cover body	No	Yes
Body depth	Stout (<30% SL)	Slender (<25% SL)

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	2.24-3.23 mm
No. of oil globules	One
Oil globule diameter	
Yolk	
Envelope	Opaque, thick
Hatch size	7-10 mm SL (9.3 mm SL)
Incubation time/temp.	
Pigment	

Diagnostic characters

LARVAE

Preanal length	~43-55% SL
Length at flexion	11-15 mm SL
Length at transformation	30 mm SL; larvae remain pelagic to 52 mm SL
Sequence of fin development	Caudal and pectorals, 2nd dorsal (rays) and anal, 1st dorsal (spines), pelvics

Pigment

- Head and snout
- Laterally on surface of gut
- Along dorsal midline and ventrolateral body
- Rather uniformly pigmented (flexion)

Diagnostic characters (see Table 3)

- Distinguished from other hexagrammids by
- Pointed snout, protruding lower jaw
 - Large terminal mouth with gape directed upward
 - Longer gut
 - Distribution of pigment on tail

Table 34
Guide for identifying Northeast Pacific species of
Hexagrammos based on meristic characters
 (Kendall and Vinter 1984).

Based on principal ventral caudal fin rays*	
Principal ventral caudal rays	8
precaudal vertebrae	20-22 = <i>H. stelleri</i>
precaudal vertebrae	18-19 = <i>H. octogrammus</i>
Principal ventral caudal rays	9 = <i>H. decagrammus</i>
Principal ventral caudal rays	10 = <i>H. lagocephalus</i>
Based on extremes of meristic characters	
Dorsal fin spinous rays	18-19 = <i>H. octogrammus</i>
	20-23 = indeterminate
	24-25 = <i>H. stelleri</i>
Dorsal fin soft rays	18-19 = <i>H. stelleri</i>
	20-25 = indeterminate
	26 = <i>H. decagrammus</i>
Total anal fin elements	21 = <i>H. lagocephalus</i>
	22-26 = indeterminate
Precaudal vertebrae	18-19 = <i>H. octogrammus</i>
	20-23 = indeterminate
Caudal vertebrae	31 = <i>H. stelleri</i>
	32-35 = indeterminate
Total vertebrae	50 = <i>H. octogrammus</i>
	51-57 = indeterminate

*Prior to completion of caudal fin development, the principal ventral caudal fin ray count can be one less in larvae.

Table 35
Pigmentation characteristics that distinguish larvae <30 mm of the four species of
Hexagrammos in the Northeast Pacific
 (Kendall and Vinter 1984, in part).^a

Species	Pigment area			
	Postanal ventral midline	Isthmus	Notochord tip	Internal pectoral fin base ^b (>17 mm)
<i>H. stelleri</i>	Absent until ~15 mm, then starts to form posteriorly (on caudal peduncle), later (>23 mm) forms along entire base of anal fin.	Absent at hatching. Anterior half gradually becomes pigmented starting at 10 mm.	Absent	Present
<i>H. decagrammus</i>	Absent until ~13 mm, then starts to form along anal fin base near its origin. By 18 mm along anal fin base to caudal peduncle. Spots more numerous and smaller than on <i>H. lagocephalus</i> .	About four equal-sized and -spaced spots form on each side making a "V." Present from ~9 mm on.	Absent at hatching but forms by ~10 mm.	Inconsistently present
<i>H. lagocephalus</i>	Present throughout development. Particularly dense on caudal peduncle. Spots along anal fin base tend not to touch each other. Spots uneven in spacing and size to create irregular line. Few spots anterior to origin of anal fin.	An anterior medial spot and about five equal-sized and -spaced spots present from ~9 mm on.	Present	Absent
<i>H. octogrammus</i>	Present throughout development. Extends from anus to base of caudal fin. Dense on caudal peduncle. Spots tend to touch each other to create a continuous straight line.	Present; anteriormost and posteriormost spots larger than others. Anterior medial spot seen at 10 mm, up to five on each side of isthmus seen at 12 mm. Spacing uneven.	Present	Present

^aPigmentation characteristics discussed in this table were based on larvae collected in the Gulf of Alaska. Variation in some of these features is known to occur in larvae from other areas.

^bOne to a few spots occur near the dorsal edge of the internal surface of the pectoral fin base.

COTTIDAE

The sculpins are represented by over 100 species within 45 genera in the study area. Most species are benthic as juveniles and adults and planktonic as larvae. Adults commonly occur in nearshore and intertidal regions throughout the study area. Cottids generally produce demersal eggs that are guarded in shallow water. Although larval cottids are commonly collected during ichthyoplankton surveys, the early life histories of most species are poorly known and larval descriptions are available for fewer than half the species. The cottid section is arranged according to the phenetic groups first described by Richardson (1981a) and recently updated by Washington et al. (1984a).¹ Preceding the taxonomic sections, the groups are briefly described, representative taxa from each group are illustrated, and a table of meristic characters is provided (Table 36). Betsy Washington provided vertebral counts for several genera based on her osteological studies of the cottids.² In most cases (except for *Clinocottus acuticeps* where $n=3$), counts were taken from one specimen.

¹Psychrolutidae (sensu J. Nelson 1984) is included within Cottidae.

COTTIDAE

PHENETIC GROUPS

Rhamphocottus (Rhamphocottus) Larvae are extremely deep-bodied with a long snout-anus length. Melanophores develop uniformly over the body except on the caudal peduncle and ventral gut surface. Small prickles develop all over the body by 9-10 mm, and only one preopercular spine develops.

Hemilepidotus-Scorpaenichthys (Hemilepidotus, Scorpaenichthys) Larvae are relatively long and slender at hatching with moderately long guts (40-60% SL) and rounded snouts. They become increasingly deep-bodied. Larvae are relatively heavily pigmented. Four prominent preopercular spines develop.

Myoxocephalus (Artedius meanyi, Ascelichthys, Chitonotus, Enophrys, Gymnocanthus, Icelinus, Icelus, Myoxocephalus, Paricelinus, Radulinus, Synchronus, Triglops) Larvae are generally slender-bodied with pointed snouts. Pigment is variable, but most members have heavy pigment on dorsal surface of the gut, nape, and along the postanal ventral midline. Larvae develop four preopercular spines and a distinct bony preopercular shelf. Parietal, nuchal, supracleithral, posttemporal, and occasionally postocular spines develop.

Artedius (Artedius other than A. meanyi; Clinocottus, Oligocottus) Larvae are stubby-bodied with a slightly humped appearance at the nape. Snouts are rounded and guts trail distinctively below the ventral body midline. Some species have gut diverticula. Pigment is relatively light, occurring on the nape, over the gut, and along the postanal ventral midline. Larvae develop a unique preopercular spine pattern with 6-24 spines (enlarged on illustrations).

ARTEDIUS

Figures A–B, E, Richardson and Washington 1980; C, Matarese and Marliave 1982; D, NWAFC original (B. Vinter).

COTTIDAE

Psychrolutes (*Gilbertidia*, *Psychrolutes*) Larvae are tadpole-shaped with large rounded heads tapering toward the tail. They possess an outer layer of flabby skin. The head, nape, gut, and pectoral fins are pigmented. No postanal ventral midline melanophores are present, but pigment is added laterally with development. Head and preopercular spines are absent.

Malacocottus (*Dasycottus*, *Malacocottus*) Similar to *Psychrolutes* group but larvae develop 4-5 preopercular spines.

Leptocottus (*Cottus*, *Leptocottus*) Larvae are relatively slender with rounded snouts and moderately short guts. Pigment is light on the postanal body. Other pigment occurs on nape, over gut, and widely spaced along the postanal ventral midline. Four weak preopercular spines develop but other head spines are lacking.

Hemitripterus (*Blepsias*, *Hemitripterus*, *Nautichthys*) Newly hatched larvae are elongate and slender, becoming deeper with development. *Nautichthys* larvae have long pigmented pectoral fins. Pigmentation is heavy, covering the body except for the caudal peduncle. Pigment extends into the dorsal and ventral finfolds. Larvae develop four prominent preopercular spines.

PHENETIC GROUPS

Diagnostic characters

LARVAE

Preanal length	>50% SL
Length at flexion	6.9-10.0 mm NL
Length at transformation	14-15 mm SL
Sequence of fin development	Dorsal, anal, and pectorals followed by caudal and pelvics

Pigment

- Larvae are uniformly covered with melanophores except for caudal peduncle and the ventral surface of gut

Diagnostic characters (see Table 3)

- Morphology: Deep-bodied, very long snout-to-anus length
- Uniformly heavily pigmented
- Presence of pigmented preanal finfold
- Prickles develop over most of body by 9-10 mm SL
- Spines: Only one preopercular (small spiny projections appear along the preopercular margin); others include parietal, nuchal, supracleithral, posttemporal, and postocular

- Dense pigment covering body except for caudal peduncle

Diagnostic characters (see Table 3)

- Develops bony bumps on areas where head spines occur in *Hemilepidotus* spp.
- Becomes increasingly deep-bodied with development
- Uniformity of pigment

Diagnostic characters

LARVAE

Preanal length	<50% SL
Length at flexion	6.2-9.4 mm SL
Length at transformation	13-19 mm SL
Sequence of fin development	Caudal, 2nd dorsal (rays) and anal, 1st dorsal (spines) and pectorals, pelvics (pectorals and pelvics formed by 11.5 mm SL)

Pigment

- Low number (<15) ventral midline melanophores
- Dorsal and anal finfolds
- Base of cleithrum

Diagnostic characters

- Short gut (33% SL)
- Pointed snout
- Pigment (see above)
- Four preopercular spines, other spines (as for *Myoxocephalus* group)
- Pelvic fin ray count I,2; visible in late-stage larvae and juveniles

^aTotal myomere count from Figures A and B = 36.

^bB.B. Washington, NMFS Systematics Lab., Natl. Mus. Nat. Hist., Wash., D.C. 20560, unpubl.

^cI,2 is the most common count. The first ray is greatly thickened and broadly branched distally, probably leading to the erroneous counts of I,3 in the literature (B.B. Washington, pers. commun., 8 Dec. 1986).

Ref: Richardson and Washington 1980 (as *Icelinus* spp.), Washington 1986, Washington et al. 1984b.

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	1.02-1.05 mm
No. of oil globules	One large, 5-8 small
Oil globule diameter	0.3 mm (large)
Yolk	
Envelope	Salmon-colored
Hatch size	2.9-3.0 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

LARVAE

Preanal length	<50% SL
Length at flexion	
Length at transformation	Begins ~16.6 mm SL
Sequence of fin development	Caudal first, pelvics last
Pigment	

- Dorsolateral gut pigment generally light according to Richardson and Washington (1980),^c but specimens we collect have heavier pigment (compare Figures A and B with C and D)
- Our specimens have heavy crown pigment

Diagnostic characters

- Number of ventral midline melanophores >40 in preflexion larvae (<6 mm SL) and >20 in others
- Upper two preopercular spines larger than lower two

^aGoldberg 1980b

^bMisitano 1980

^cRichardson suspects Figures C and D are incorrect; series requires reevaluation (S.L. Richardson, deceased, pers. commun., Oct. 1984). Washington suspects they are *Icelinus*, probably *I. quadriseriatus*, which occurs outside our study area (B.B. Washington, NMFS Systematics Lab., Natl. Mus. Nat. Hist., Wash., D.C. 20560, pers. commun., 8 Dec. 1986).

Figures A–C, Richardson and Washington 1980.

Presently we cannot identify to species *Gymnocanthus* larvae from samples collected in our study area. We identify one type, *Gymnocanthus* A, and include illustrations of *G. hertzensteini* for comparison. Generic characters include:

- Patch of pigment on crown
- Heavy dorsal pigment on gut, increasing dorsolaterally with development
- Numerous, closely spaced, ventral midline melanophores in preflexion larvae

The following meristic information may aid in their identification.

Species	Distribution	Vertebrae	Fins				
			Dorsal		Anal rays	Pectoral rays	Pelvic rays
			Spines	Rays			
<i>Gymnocanthus detriscus</i>	Bering Sea	37-39	IX-XI	15-18	15-19	19-20	I,3
<i>Gymnocanthus galeatus</i>	Brit. Col. - Bering Sea	37-40	X-XII	14-17	17-20	19-21	I,3
<i>Gymnocanthus pistilliger</i>	SE Alaska - Bering Sea	35-38	IX-XI	13-16	14-18	15-20	I,3
<i>Gymnocanthus tricuspis</i>	Bering Sea - Arctic	36-40	X-XII	15-17	15-18	17-20	I,3

Diagnostic characters

LARVAE

Preanal length
Length at flexion
Length at transformation
Sequence of fin development
Pigment^b

- Heavy pigment on crown and dorsolateral surface of gut
- Larvae >12.2 mm SL have pigment along dorsal midline, and larvae >13.9 mm SL develop pigment along lateral line
- Ventral midline melanophores are widely spaced anteriorly and closely spaced posteriorly

Diagnostic characters

- Specimens of other species of *Gymnocanthus* at comparable developmental stages have not been described

^aAndriashev 1954

^bSpecimens have not been collected from our study area. Illustrations of out-of-area specimens are presented for comparison and may differ.

Ref: Andriashev 1954, Khan 1972, Washington et al. 1984b.

Figures A–E (C, dorsal view; E, ventral view), Khan 1972 (Atlantic specimens, redrawn).

Eggs and larvae of *Icelinus* spp. from the study area are unknown. Illustrations of *Icelinus* A and B, both tentatively identified as *I. borealis* by Washington and Richardson (unpubl.),¹ are presented here.

The following meristic characters may aid in their identification.

Species	Distribution	Vertebrae	Fins				
			Dorsal		Anal rays	Pectoral rays	Pelvic rays
			Spines	Rays			
<i>Icelinus borealis</i>	Wash. - Bering Sea	35-36	IX-XI	14-17	11-14	14-17	I,2
<i>Icelinus burchami</i>	S. Calif. - SE Alaska	35-37	X-XI	16-18	12-14	16-19	I,2
<i>Icelinus filamentosus</i>	S. Calif. - Gulf of Alaska	34-37	X-XII	15-17	13-16	16-18	I,2
<i>Icelinus fimbriatus</i>	S. Calif. - Brit. Col.	37	XI	15-17	13-14	17	I,2
<i>Icelinus tenuis</i> *	SSC - Brit. Col.	37-39	IX-XI	16-18	14-17	15-17	I,2

*A partial series of *I. tenuis* larvae has been identified at Los Angeles County Museum (R. Feeney, Los Ang. Cty. Mus. Nat. Hist., 900 Exposition Blvd., Los Angeles, CA 90007, pers. commun., Oct. 1986).

Eggs and larvae of *Icelus* spp. from our study area are unknown. The following meristic characters may aid in their identification.

Species	Distribution	Vertebrae	Fins				
			Dorsal		Anal rays	Pectoral rays	Pelvic rays
			Spines	Rays			
<i>Icelus canaliculatus</i>	Gulf of Alaska - Bering Sea	41	VII-VIII	22-25	18-20	15-19	I,3
<i>Icelus euryops</i>	Gulf of Alaska - Bering Sea		VIII-X	20-23	15-19	16-18	I,3
<i>Icelus scutiger</i> *	Gulf of Alaska - Bering Sea	39-41	IX-X	18-21	17-19	17-19	I,3
<i>Icelus spatula</i>	Gulf of Alaska - Arctic	39-41	VII-X	17-22	13-18	16-20	I,3
<i>Icelus spiniger</i>	Brit. Col. - Bering Sea	40-42	VIII-X	19-24	15-20	17-20	I,3
<i>Icelus uncinalis</i>	Bering Sea	37-40	IX-X	18-20	14-16	17-18	I,3

*Placed in the genus *Rastrinus* by D.W. Nelson (1984).

Presently we cannot identify to species *Myoxocephalus* larvae from samples we collect in our study area. We collect at least two types based on the following pigmentation characters:

***Myoxocephalus* B** Ventral midline melanophore series (>40 spots), dorsal pigment on gut, and crown pigment; with development, dorsolateral pigment appears covering about 2/3 body length, small ventrolateral patch appears at midbody. Ventrolateral body from over gut to about six myomeres after anus is unpigmented.

***Myoxocephalus* G (probably *M. polyacanthocephalus*)** Preflexion pigment pattern similar to flexion pattern of the other *Myoxocephalus* type; crown, gut, and ventral midline series with dorsolateral and lateral pigment covering 2/3 body length. Body pigment becomes more intense and crown pigment covers entire head with development. No unpigmented area on lateral body over gut and anus.

The following meristic characters may aid in their identification.

Species	Distribution	Vertebrae	Fins				
			Dorsal		Anal rays	Pectoral rays	Pelvic rays
			Spines	Rays			
<i>Myoxocephalus axillaris</i> *	Bering Sea - Arctic		VIII-X	15-17	11-13	14-16	I,3
<i>Myoxocephalus brandti</i>	Bering Sea		IX	15	12-13	16-17	I,3
<i>Myoxocephalus jaok</i>	Gulf of Alaska - Chukchi Sea	35-38	VIII-XI	13-17	12-16	17-19	I,3
<i>Myoxocephalus niger</i>	Bering Sea	36-39	VIII-X	14-18	10-12	16-18	I,3
<i>Myoxocephalus polyacanthocephalus</i>	Wash. - Bering Sea	34-37	IX-X	10-15	8-13	16-19	I,3
<i>Myoxocephalus quadricornis</i>	Bering Sea - Arctic	38-42	VII-X	12-16	13-17	14-18	I,3
<i>Myoxocephalus scorpioides</i> *	Bering Sea - Arctic	35-38	VIII-X	13-18	10-14	14-17	I,3
<i>Myoxocephalus scorpius</i> *	SE Alaska - Arctic	38-46	VIII-XII	12-20	10-16	16-19	I,3
<i>Myoxocephalus stelleri</i>	Bering Sea - Chukchi Sea		VIII-X	15-16	11-14	16-18	I,3
<i>Myoxocephalus verrucosus</i> *	Brit. Col. - Arctic		IX-XII	15-18	13-15	16-19	I,3

*According to Neelov (1979), *M. scorpioides* = *M. axillaris*, and *M. scorpius* in the study area is *M. verrucosus*.

Ref: Marliave et al. 1985.

Figures A–B, Marliave et al. 1985; C–D, NWAFC originals (B. Vinter).

Presently we cannot identify to species *Triglops* spp. larvae from samples we collect in our study area. Illustrations of *Triglops* sp. (designated as B here) (Richardson and Washington 1980) and *Triglops* A (Washington and Richardson, unpubl.¹) are presented here. Generic characters include:

- High myomere count (>45)
- Pointed snout
- Heavy dorsolateral pigmentation on gut
- Postanal ventral midline melanophores, probably becoming embedded in postflexion larvae (except *Triglops* B as figured by Richardson and Washington [1980]).

The following meristic information may aid in their identification.

Species	Distribution	Vertebrae	Fins				
			Dorsal		Anal rays	Pectoral rays	Pelvic rays
			Spines	Rays			
<i>Triglops forficata</i>	Gulf of Alaska - Bering Sea	52-54	IX-XI	27-32	27-32	20-22	I,3
<i>Triglops jordani</i>	Bering Sea		IX-XI	24-28	23-29	19-21	I,3
<i>Triglops macellus</i>	Wash. - Bering Sea	51	X-XI	27-31	27-31	15-17	I,3
<i>Triglops metopias</i>	SE Alaska - Bering Sea	48-49	X-XI	23-27	22-27	18-22	I,3
<i>Triglops pingeli</i>	Wash. - Arctic	46-48	IX-XIII	22-28	20-28	16-19	I,3
<i>Triglops scepticus</i>	SE Alaska - Bering Sea	45-46	X-XII	21-23	22-24	17-19	I,3

^bMarliave 1975a

^cPigment patterns within the genus *Artedius* appear to be highly variable. Reared specimens vary between hatches and stages (J. Marliave, Vancouver Public Aquarium, P.O. Box 3232, Vancouver, B.C., Canada V6B 3X8, pers. commun., 16 Oct. 1986). Wild specimens collected from Yaquina Bay, Oregon, show variations from the pigment patterns described in Washington (1986) (B. Mundy, NMFS Southwest Fish. Cent., Honolulu Lab., 2570 Dole St., Honolulu, HI 96822, pers. commun., 1 Oct. 1986).

Ref: Marliave 1975a; Richardson and Washington 1980 (see *Artedius* 2); Washington 1981, 1986.

Length at flexion	7.2-7.6 mm SL
Length at transformation	7.5-10.0 mm SL
Sequence of fin development	Caudal, dorsal and anal rays, dorsal spines, pectorals, pelvics

Pigment^c

- Head and nape
- Dorsolateral surface of gut
- Postanal ventral midline series, with development becoming more closely spaced posteriorly

Diagnostic characters

- Bubble of skin anterior to origin of dorsal finfold
- Distinguished from *O. snyderi* by
- Ventral midline melanophores (>15)
- Bubble of skin pigmented

Eggs and larvae of *O. rimensis* are unknown. The following information will aid in identification.

Total vertebrae	34-37
Precaudal	11-13
Caudal	22-25
Dorsal fin spines	8-10
Dorsal fin rays	16-19
Anal fin rays	13-15
Pectoral fin rays	13-15
Pelvic fin rays	3
Range	SSC-SE Alaska

A

B

Bump similar to *Artemius* but does not develop into a distinct diverticula

C

LIFE HISTORY

Range	South of southern California to SE Alaska, 55-59°N
Ecology	Intertidal, nearshore shelf demersal
ELH pattern	Oviparous, demersal eggs, pelagic larvae
Spawning	Season: Winter-spring; fall in more northerly populations ^a Area: Mode: Internal fertilization (spawn twice/season) ^a Migration:
Fecundity	Range/function:
Age at first maturity	<1 yr ^a
Longevity	>2 yr ^a

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	1.2-1.3 mm
No. of oil globules	
Oil globule diameter	
Yolk	
Envelope	
Hatch size	4.47 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

LARVAE

Preanal length	<45% SL
Length at flexion	6.2-8.4 mm SL
Length at transformation	11-13 mm SL
Sequence of fin development	Caudal, dorsal and anal rays, dorsal spines, pectorals, pelvics

Pigment

- Head and nape very lightly pigmented
- Dorsolateral surface of gut
- Ventral midline series with <10 evenly spaced melanophores

Diagnostic characters

- Spines
 - Patch of parietal spines
 - 10-12 spines develop along preopercular margin
 - 8-10 accessory spines form anteriorly at the bases of the preopercular spines
- Distinguished from *O. maculosus* by
 - Bubble of skin anterior to origin of dorsal finfold unpigmented and less obvious than *O. maculosus*
 - Ventral midline melanophores (<10)

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter
No. of oil globules
Oil globule diameter
Yolk
Envelope
Hatch size
Incubation time/temp.
Pigment

Diagnostic characters

LARVAE^b

Preanal length 58% SL, increasing with
development to 79% SL
Length at flexion ~9.8 mm SL
Length at transformation >13.4 mm SL
**Sequence of fin
development**
Pigment

- Larvae are pigmented over entire body except at the tail tip; dorsal and anal finfolds and the distal portion of the pectoral fin are unpigmented

Diagnostic characters

- Lack of head spines
- Prickles over body
- Globose morphology unlike any other cottid
- Loose outer skin
- Pelvic fin appears to be inserted in pockets of skin with only the tips exposed

Meristic characters of Cottoid A specimens agree with those of *Psychrolutes phrictus* (pectoral rays = 26, branchiostegals = 7), but identification is tentative until additional material is available (see discussion in Richardson and Washington [1980]).

^aBased on three specimens (9.8, 12.8, 13.4 mm SL) collected off Oregon.

^bTentative placement in *Psychrolutes* group.

Figures A–B, Richardson and Washington 1980.

LIFE HISTORY

Range	S. California, 32-34°N, to Gulf of Alaska, 54-60°N
Ecology	FW or anadromous type
ELH pattern	Oviparous; demersal, adhesive eggs; pelagic larvae
Spawning	Season: Jan-Apr; ^a Feb-July ^b Area: Under rocks ^b Mode: Polygamous males, eggs guarded ^b Migration: Downstream in spring to spawn ^b
Fecundity	Range/function: 280-10,980 ^a
Age at first maturity	
Longevity	>7 yr ^b

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	1.4-1.6 mm
No. of oil globules	One large, some small
Oil globule diameter	0.2-0.3 mm
Yolk	Homogeneous; granular ^a
Envelope	Thick, transparent, orange
Hatch size	4.5-5.0 mm SL; ^a 5.5-6.3 mm SL ^c
Incubation time/temp.	15-16 d/12°C
Pigment	

Diagnostic characters

LARVAE

Prenal length	40% SL
Length at flexion	~7 mm SL
Length at transformation	10 mm SL
Sequence of fin development	Pectorals and pelvics by 10 mm SL
Pigment	

- Dorsal and ventral gut surface
- Postanal ventral midline series decreasing in number and becoming more evenly spaced with development

Diagnostic characters

- Morphology: Slender, round snout
- Spines: Four preopercular, without other head spines
- Gut shape unique, posteriorly forked

Larvae of *C. aleuticus* are unknown. Spawning takes place primarily in freshwater and larvae may not occur in coastal marine plankton.

AGONIDAE

Poachers and alligatorfishes range from Baja California to the Bering Sea, with the center of abundance in the North Pacific. They are mostly elongate with large fused bony plates covering the body. Pectoral fins are fanlike. Adults are demersal and occur from moderate depths to 1250 m. Some have also been found in tidepools (Hart 1973, Garrison and Miller 1982). The family is represented by 25 species and 15 genera within the study area. Among the few species studied, demersal adhesive eggs are attached to holdfasts of laminarians (Breder and Rosen 1966, Garrison and Miller 1982). Larvae are pelagic and are occasionally taken in plankton nets near the surface. Bony plates, characteristic of agonids, first appear in the larvae as spines. Settlement in some species may occur at approximately 2 months after hatching (Marliave 1975a). Descriptions of larvae of three species are available for inclusion here (*Agonomalus mozinoi*, *Bothragonus swani*, and *Xeneretmus latifrons*). Illustrations of single specimens are provided for *Stellerina*, *Hypsagonus*, *Ocella*, *Aspidophoroides* (species outside study area), and an unidentified agonid. Two illustrations are provided for Agonidae A, another unidentified agonid from the study area.

Table 39
Meristic characters of family Agonidae. All have pelvic counts of 1,2 and 6 branchiostegal rays.

- Long slender body compared with *Bothragonus swani*

^aMarliave 1975a^bFitch and Lavenberg 1968^cJ. Marliave, Vancouver Public Aquarium, P.O. Box 3232, Vancouver, B.C., Canada V6B 3X8, pers. commun., 16 Oct. 1986.

Figures A–B, D, Marliave 1975a (D, length in Marliave 1975a is given as 21.0 mm TL [footnote c]) ; C, Washington et al. 1984b.

The family Cyclopteridae is composed of two subfamilies: the Cyclopterinae (lumpsuckers) and the Liparidinae (snailfishes). Although both subfamilies possess a ventral sucking disc, many differences distinguish the two groups (e.g., lumpsuckers have 2 dorsal fins and about 23-29 vertebrae, and snailfishes have a single dorsal fin and about 38-86 vertebrae).

Cyclopterinae

Cyclopterines are found exclusively in the cooler waters of the Northern Hemisphere. The subfamily is represented by eleven species in five genera in the Northeast Pacific and Bering Sea. Mostly benthic, adults may be found clinging to rocks in tidal zones or in rocky habitat as deep as 225 m (Hart 1973). Eggs, which are adhesive, 1.9-5.0 mm in diameter, and may contain one or more oil globules, are laid in nest sites within rocky crevices or shells and are guarded during incubation (Able et al. 1984). Newly hatched larvae may be identified as cyclopterines by their stout body shape, heavy pigmentation, large sucking disc on the ventral surface, and advanced state of development. They are found attached to substrate and prefer areas with current (A.C. Matarese and S.F. Borton, unpubl.). Larvae of only two species can be identified in our area, *Aptocyclus ventricosus* and *Eumicrotremus orbis*.

Table 40
Meristic characters of subfamily Cyclopterinae. All have pelvic discs and six branchiostegal rays.

CYCLOPTERIDAE

Liparidinae

This large subfamily is circumpolar about both poles in distribution. Within the study area there are 74 described species within 14 genera. Adults are demersal or pelagic and have been found from tidepools to depths of 7000 m (Hart 1973, Able et al. 1984). Spawning habits are diverse. Adhesive clumps of eggs (1-8 mm) have been seen attached to algae, mollusc shells, and tubeworms; eggs and larvae of *Careproctus* spp. have been found in gill cavities of lithodid crabs (Anderson and Cailliet 1974). Parental care of eggs (i.e., hiding, paternal guarding, or both) is exhibited in most taxa studied. Most species studied, especially deep-water forms, hatch at an advanced stage of development (Able et al. 1984). Larvae are planktonic or benthic. Only one complete larval series is available from our area, *Rhinoliparis barbulifer*. Illustrations of two unidentified larvae are provided since each of them is relatively common in our collection. The small larva (4.0 mm SL) is common in our Gulf of Alaska collections whereas the larger larva (5.8 mm SL) is routinely collected in our surveys along the Pacific Coast and represents one of the ten most abundant groups of ichthyoplankton collected off Oregon (Mundy, pers. commun.)¹. Representatives of specimens from other areas (Atlantic, Arctic) are presented for three genera: *Careproctus*, *Paraliparis*, and *Liparis*. Early juvenile specimens of *Paraliparis* sp. (probably *P. deani*) are occasionally collected in plankton nets. Illustrations of a tentatively identified partial series of *Nectoliparis pelagicus* are also provided.

^aThe NWAFC meristic database was updated for the Liparidinae by the papers of Kido (1983, 1984, 1985), Kido and Kitagawa (1986), and unpublished data from D. Stein (Oregon St. Univ., Corvallis, OR 97331, pers. commun., 29 Oct. 1986).

^bAt least two undescribed species in addition to *A. opercularis* probably occur in the Bering Sea.

^cAccording to Soldatov and Lindberg (1930), *Liparis mednius* has six dorsal spines.

MERISTICS

Vertebrae	Total: 61-X-64 Precaudal: 9-X-12 Caudal: 50-X-52
Branchiostegal rays	5-5-5
Caudal fin	
Pelvic fin	Absent
Dorsal fin	R: 44-X-56
Pectoral fin	R: 19-20-25
Anal fin	R: 40-X-51
Gill rakers	U: X-X-X L: X-X-X

LIFE HISTORY

Range	Cent. California, 34-38°N, to Bering Sea, 54-66°N
Ecology	Nearshore shelf demersal
ELH pattern	Oviparous, eggs probably demersal, pelagic larvae
Spawning	Season: Area: Mode: Migration:
Fecundity	Range/function:
Age at first maturity	
Longevity	

EARLY LIFE HISTORY DESCRIPTION**EGGS**

No. of oil globules
Oil globule diameter
Yolk
Envelope
Hatch size
Incubation time/temp.
Pigment

Diagnostic characters**LARVAE^a**

Preanal length Changes with development
Length at flexion
Length at transformation
Sequence of fin development
Pigment

- Darkly pigmented peritoneum
- Ventral half of head pigmented, appearing bearded

Diagnostic characters

- Presence of two separate pectoral fin lobes
- General tadpole shape
- Position of anus: Apparently moves forward with development; in adults anus is directly under eye
- Absence of disc
- Number of branchiostegal rays (five)

^a Identification of small larvae prior to pectoral fin development and movement of anus forward is tentative. A cleared and stained 7.9-mm SL specimen has five branchiostegal rays.

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	2.5 mm
No. of oil globules	
Oil globule diameter	
Yolk	
Envelope	
Hatch size	≤9.1 mm SL
Incubation time/temp.	
Pigment	• Unpigmented

Diagnostic characters

- Yolk absorbed by 11.7 mm SL
- Flexion and fin ray development occurs prior to hatching

LARVAE (postflexion and juvenile)

Preanal length	<50% SL
Length at flexion	<9.1 mm SL
Length at transformation	
Sequence of fin development	Dorsal, anal, and caudal; pectoral

Pigment

- Larvae <11.0 mm SL have no pigment
- Nape, peritoneum, and lateral body pigmented by 12.5 mm SL
- Pigment on the head and body increases in larger specimens

Diagnostic characters

- Loose skin over body
- Morphology
 - Depressed head
 - Large snout
 - Slender tapering body
- Absence of disc

Perciformes

The most diversified of all fish orders is the Perciformes. Although the order encompasses the entire range of fish forms and behavior, most species are adapted for life as predators in shallow or surface waters. More than a dozen characters (many secondarily lost) define this group of spiny-rayed fishes. Most obvious of these are fin spines, two dorsal fins, scales generally ctenoid, pelvic fin inserted forward of the abdomen, and vertical insertion of the pectoral fin. There are 22 suborders, 150 families, 1,367 genera, and about 7,800 species within the order (J. Nelson 1984). The most speciose groups are the percoids and zoarcoids. Within the study area, nine suborders are represented; four of them are composed of a single species. Most species are members of the families Stichaeidae and Zoarcidae.

Some early-life-history stages are known for most families within our area except for Zoarcidae and Scytalinidae. When describing the sequence of fin ray development for percoids, we used the patterns A-F summarized in G.D. Johnson (1984) (see also Introduction, p. 29). A summary of meristic characters of zoarcids is provided to assist in identification.

Families in study area:	Carangidae	Zaproridae
	Bramidae	Scytalinidae
	Caristiidae	Trichodontidae
	Sciaenidae	Clinidae
	Pentacerotidae	Icosteidae
	Bathymasteridae	Ammodytidae
	Zoarcidae	Gobiidae
	Stichaeidae	Trichiuridae
	Cryptacanthodidae	Scombridae
	Pholididae	Luvaridae
	Anarhichantidae	Stromateidae
	Ptilichthyidae	Centrolophidae
		Tetragonuridae

MERISTICS

Vertebrae	Total: 25-25-25

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	~1.3 mm
No. of oil globules	
Oil globule diameter	
Yolk	
Envelope	Smooth
Hatch size	
Incubation time/temp.	24-48 hr/18-30°C
Pigment	

Diagnostic characters

LARVAE

Preanal length	~50-75% SL
Length at flexion	>4.1 mm SL
Length at transformation	
Sequence of fin development	“A” pattern: ^b 2nd dorsal (rays), anal, and caudal simultaneously followed by 1st dorsal (spines), pelvics, and pectorals (some carangids have precocious pelvics)

Pigment

- Uniform heavy pigmentation
- Body: Dorsolateral, lateral midline, and scattered on ventrolateral
- Vomer and branchiostegal membrane
- Antimedial rows on dorsal body margin present or absent^c

Diagnostic characters

- Relatively deep bodied
- Uniform heavy pigment except in caudal region
- Pigment on branchiostegal membrane
- 25 myomeres
- Flexion and postflexion
 - Large posttemporal and supracleithral, supraocular and preopercular spines (not serrate)
 - No supraoccipital crest

^aThe first two spines are physically separated from the third, shorter spine which is associated with the anal fin soft rays.

LIFE HISTORY

Range	South of southern California to Gulf of Alaska, 54-60°N
Ecology	Epi- and mesopelagic, 0-403 m ^b
ELH pattern	Oviparous, pelagic eggs, pelagic larvae
Spawning	Season: Jan-Nov; ^c Mar-Aug (California) ^d Area: Epipelagic, offshore ^e Mode: Migration:
Fecundity	Range/function: 53,000 ^b
Age at first maturity	2-3 yr ^e
Longevity	>30 yr ^e

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	0.90-1.08 mm
No. of oil globules	One
Oil globule diameter	0.25 mm
Yolk	Segmented
Envelope	Smooth, clear
Hatch size	1.91-2.38 mm SL
Incubation time/temp.	24-48 hr/18-30°C
Pigment	
	• Oil globule
	• Dorsal and ventral melanophores

Diagnostic characters

- Anterior position of oil globule in yolksac larvae
- Pigment
- Lack of yolk pigment distinguishes eggs from *Merluccius productus* (p. 186) and *Scomber japonicus* (p. 554)

LARVAE

Preanal length	52-61% SL ^f
Length at flexion	8-11 mm SL
Length at transformation	16 mm SL
Sequence of fin development	“A” pattern: ^g 2nd dorsal (rays), anal, and caudal simultaneously followed by 1st dorsal (spines), pelvics, and pectorals (some carangids have precocious pelvics)

Pigment

- Crown, dorsal and ventral midline
- Mediolateral streak
- Some superficial lateral pigment develops

Diagnostic characters

- Low myomere count (usually 24)
- Dorsal body margin pigment; antimedial rows absent with median rows only
- Flexion and postflexion
 - ~9 preopercular spines (not serrate)
 - Supraoccipital crest present

^aThe first two spines are physically separated from the third, shorter spine which is associated with the anal fin soft rays.

^bHart 1973

^cFrey 1971

^dMacCall and Stauffer 1983

^eFitch and Lavenberg 1971

^fRemains within this range from 2.2 to 50.0 mm SL.

Spawning	Season: Area: Mode: Migration:
Fecundity	Range/function:
Age at first maturity	
Longevity	

^a *Pentaceros* = *Pseudopentaceros* (Hardy 1983). J. Nelson (1984) does not recognize the genus *Pseudopentaceros* and cites Smith (1964) who included *Pseudopentaceros* in the synonymy of *Pentaceros*. Hardy (1983) removed *Pseudopentaceros* from synonymy but his work is not cited in J. Nelson (1984). The genus *Pseudopentaceros* may include up to three species:

Pseudopentaceros richardsoni—Restricted to Southern Hemisphere

P. wheeleri—North Pacific Ocean from Japan to Hawaii

P. pectoralis—North Pacific, Hawaii to Aleutian Is. (overlaps with *P. wheeleri* in central Pacific)

Hardy (1983) describes *P. wheeleri* as the most slender form. He suggests they are the "slender forms" referred to by Zama et al. (1977a) in their description of *Pentaceros richardsoni*. Hardy does not synonymize their "high-bodied" forms with *P. wheeleri*. The juvenile form described by Zama et al. (1977a) may include *P. wheeleri* in part. Hardy (1983) names this species as the one targeted on the Hawaiian ridge for intense commercial fishing. *Pseudopentaceros wheeleri* and *P. pectoralis* are probably the same species at different ontogenetic stages. Most likely two species occur worldwide (Humphreys et al. 1989).

^b Hardy 1983; includes meristic data for *Pseudopentaceros richardsoni*, *P. pectoralis*, and *P. wheeleri*.

^c Juveniles collected at surface to at least 260 mm FL; the shift from pelagic to bottom life may be ambivalent, occurring between 260 and 300 mm FL.

Ref: Hardy 1983, Humphreys et al. 1989, G.D. Johnson 1984, Zama et al. 1977b.

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter
No. of oil globules

Diagnostic characters**LARVAE**

Preanal length
Length at flexion <9 mm SL
Length at transformation
Sequence of fin
development
Pigment (early juvenile *P. richardsoni*)

- Entire body heavily pigmented with intense patches along dorsal body midline and on spinous dorsal, anal, and pelvic fins

Diagnostic characters (early juvenile *P. richardsoni*)

- Pigment pattern
- Bony cranial projections, spines by 10-16 mm SL; most prominent are the following: median supraoccipital; posttemporal; lateral expansions which develop over orbit, becoming highly serrated along the edge with development; preopercular
- Anteriorly serrated pelvic spine
- With development there is a reduction in spination

Figure A, G.D. Johnson 1984 (southern hemisphere specimen).

BATHYMASTERIDAE

This endemic North Pacific family occurs throughout the study area where four species from two genera are found. Ronquils are elongate with long dorsal and anal fins composed almost entirely of soft rays. Little is known of the adult habits in the family except for some members of the genus *Rathbunella*, occurring from south of Point Conception to northern California, which inhabit rocky areas 10-92 m deep (and are occasionally taken with trawl nets). Courtship of *Rathbunella* is paired and may result in spawning occurring over a protracted period of time. Demersal eggs, which measure 0.9-1.1 mm and contain one oil globule, are deposited in a nonadhesive mass that is guarded by the male (Fitch and Lavenberg 1975, NWAFU unpubl.).

Pelagic larvae of *Ronquilus jordani* are collected in ichthyoplankton surveys conducted off Alaska and along the Pacific coast to northern California. *Bathymaster* spp. (6-40 mm SL) are routinely collected in the Gulf of Alaska and in the Bering Sea. *Ronquilus* larvae can be separated from *Bathymaster* larvae by their lack of pigment around the urostyle. *Bathymaster* spp. larvae are presently not identifiable to species. Meristic characters offer some potential for larger larvae (e.g., *B. signatus* usually has higher counts, especially vertebrae and total caudal fin rays). Before their fin rays develop, bathymasterid larvae may often be confused with stichaeid larvae. Most stichaeids (except members of the Stichaeini tribe) have a myomere count >55, whereas bathymasterids have a count <55. *Ronquilus jordani* larvae (myomeres 49-50) most closely resemble *Stichaeus punctatus* larvae (myomeres 51-55) due to the presence of distinctive lateral pigment along the hypaxial myomeres. *Bathymaster* spp. larvae (myomeres 49-55) most closely resemble those of *Bryozoichthys-Chirolphis* (myomeres about 60-75) due to the presence of pigment around the urostyle.

Table 42
Meristic characters of family Bathymasteridae.^a All have pelvic fin counts of I,5, 7+7 principal caudal fin rays, and 6 branchiostegal rays.

Taxon	Distribution	Vertebrae		Fins

Ronquilus jordani

Figures A–D, NWAFC originals (B. Vinter).

ZOARCIDAE

Eelpouts are found chiefly in colder marine waters of the Northern Hemisphere. They have elongate, tapered bodies with long dorsal and anal fins confluent with the caudal fin. The pelvic fins are small and jugular when present. The head is large and the mouth is often big with thick lips. Within the study area there are 48 species within 14 genera. Adults are found from the intertidal zone to depths of more than 1900 m (Hart 1973). Although members of the genus *Zoarces* are viviparous, all species in our area, where reproductive mode is known, are oviparous. Oviparous species have been observed guarding their eggs by wrapping themselves around the egg mass. Demersal eggs are adhesive, spherical, and possess one oil globule. Diameters range from 1.7 to 9.0 mm. Newly hatched larvae are quite advanced and strongly resemble adult zoarcids (Anderson 1984b). Larvae of only five taxa have been illustrated; four are from outside the study area. Larvae probably become demersal or semidemersal soon after hatching because they are virtually never collected in plankton nets.

STICHAEIDAE

Pricklebacks are found mostly in the North Pacific in inshore areas. Adults are long and somewhat eel-like with a long dorsal fin composed of all spines in most species. Seventeen genera and 26 species are found in the study area. This family is separated into eight tribes grouped within four subfamilies. Six tribes within three subfamilies occur in our area.¹ Larvae are abundant in the area but very few larval series have been described. Before fin rays develop, small larvae are elongate and resemble other elongate forms, especially bathymasterids and pholidids (see Table 4). In general, bathymasterids have fewer myomeres and pholidids have a longer gut and more myomeres. Since so few complete larval series are available, general characters based on only a few species are presented for each tribe.

Stichaeinae

Adult characters include: Pelvic fins I,3-4
(*Gymnoclinus* I,2)
Large pectoral fins
Vertebrae 49-76

Stichaeini

Genera found within the study area: *Eumesogrammus* (one species) and *Stichaeus* (one species). Myomere counts are low (<55). *Stichaeus* larvae are identified by the distinctive lateral pigment along the hypaxial myomeres.

Chirolophini

Genera found within the study area: *Bryzoichthys* (two species), *Chirolophis* (four species), and *Gymnoclinus* (one species). Myomere counts are >55. Larvae are generally more pigmented than Stichaeini. Melanophores occur along the dorsal and ventral body midline, over the notochord internally, and, in some taxa, around the urostyle.

¹Makushok (1958) places the genera *Eulophias* and *Azygopterus* in separate tribes under Xiphisterinae. Anderson (1984b) places them together in the Eulophiini. Other nomenclatural changes not affecting taxa in the study area are presented by Yatsu (1986).

CHIROLOPHINI
Bryozoichthys–Chirolophis

C

D

Figures A–B (B, ventral view), Fahay 1983 (after Faber 1976, North Atlantic specimen); C–D, NWAFC originals (B. Vinter).

STICHAEIDAE

Lumpeninae

Adult characters include: Pelvic fins I,3 or absent
Large pectoral fins
Vertebrae 60-81

Lumpenini

Genera found within the study area: *Acantholumpenus* (one species), *Anisarchus* (one species), *Lumpenella* (one species), *Lumpenus* (four species), and *Poroclinus* (one species). Lumpenini larvae generally lack pigment along the dorsal midline. Diagnostic pigment usually occurs over the dorsal surface of the gut and anus, along the ventral midline, and in the hypural area.

Lumpenella larvae generally have >70 myomeres and pigment around the urostyle, and, with development, can be identified by their distinctive snout and the presence of up to five anal spines. *Lumpenus* spp. larvae can be identified by meristics, number of postanal ventral melanophores, and number of melanophores on the anus. Hypural pigment is usually restricted to several spots along the posterior edge of the hypural area. *Poroclinus* larvae have distinctive pigment occurring above and below the notochord in the caudal peduncle area. They can also be distinguished from other Lumpenini by the presence of three anal spines.

LUMPENINI

Lumpenella longirostris

Lumpenus maculatus

Lumpenus sagitta

Poroclinus rothrocki

Figures A, C, F, Garrison, unpubl.; B, Fahay 1983 (after Faber 1976, Atlantic specimen); D-E, NWAFC originals (B. Vinter).

STICHAEIDAE

Opisthocentrini

Genera found within the study area: *Allolumpenus* (one species), *Opisthocentrus* (one species), and *Plectobranchnus* (one species). Larvae are known only for *Opisthocentrus* and *Plectobranchnus*. *Plectobranchnus* larvae have a distinctive pigment pattern quite dissimilar to *Opisthocentrus* (see species pages). *Opisthocentrus* larvae appear to resemble Alectrini larvae (e.g., similar pigment pattern and lack of pelvic fins).

Xiphisterinae

Adult characters include: Pelvic fins absent
Pectoral fins small
Vertebrae 57-84

Alectrini

Genera found within the study area: *Aletridium* (one species) and *Anoplarchus* (two species). Only larvae of *Anoplarchus purpurescens* are known from our area. They have a row of postanal ventral midline melanophores and a few spots along the hypural margin. No single unique character distinguishes them from Xiphisterini larvae but usually a combination of characters allows identification. These characters include fewer myomeres (58-68 vs. generally >70), smaller relative eye diameter, fewer melanophores dorsally on gut, and presence of hypural spots throughout the larval period (see species pages).

Xiphisterini

Genera found within the study area: *Cebidichthys* (one species), *Phytichthys* (one species), and *Xiphister* (two species). Although series of *Phytichthys* and *Xiphister* have been described, larvae are difficult to distinguish from one another and from *Anoplarchus*. Xiphisterini larvae usually have a row of postanal ventral melanophores and a row of internal pigment above the notochord.

B *Lyconectes aleutensis*

Figures A–B, NWAFC originals (B. Vinter).

PHOLIDIDAE

Although some species of gunnels are found in the North Atlantic, most members of this family are located in the eastern Pacific. Pholidids are eel-like with long compressed bodies, a dorsal fin extending from head to caudal fin and made up entirely of spines, and small pelvic fins (I,1) when present. There are nine species in three genera within the study area.¹ Adults are demersal, occurring from as deep as 75 m to tidepools (Hart 1973). Pholidids are noted for paired spawning and subsequent guarding of eggs which may be 1.4-3.0 mm and have one oil globule (A.C. Matarese, unpubl.). One or both partners may guard the eggs during incubation by coiling around them (Breder and Rosen 1966). Larvae are pelagic and may settle after 50 days (Garrison and Miller 1982).

Presently, larvae of *Pholis* spp. cannot be identified to species in our study area. The following characters may be helpful in separating *Pholis* spp. larvae from those of *Apodichthys flavidus*.

Morphology Head and eye generally smaller in *Pholis* at comparable stages of development

Meristics Presence of pelvic fins and two anal spines in *Pholis*

Pigment Internal pigment above notochord is less pronounced and disappears sometime before larvae undergo flexion; presence of a continuous series of melanophores along ventral surface of gut; pigment spots along dorsal surface of gut are smaller and more numerous (postflexion)

Meristic characters may be useful in separating larger *Pholis* postflexion larvae and juveniles. Off Washington, Oregon, and California, myomere counts enable separation of *P. clemensi* (94-98) and *P. schultzi* (89-93) from other species (usually <90).

Larvae of *Xererpes fucorum* are inadequately known. *X. fucorum* can be separated from *Pholis* spp. by their lack of pelvic fins and from *Apodichthys flavidus* by the presence of one or two anal spines and a lower dorsal spine count (83-87 vs. 90-94).

¹Yatsu (1985) proposes alternative generic placements for several species; according to his arrangement, nine species within four genera occur in the area.

Table 45
Meristic characters of family Pholididae.*

Taxon	Distribution	Vertebrae		Fins				Gill rakers		Branchiostegals
		Precaudal (Total)	Caudal	Dorsal	Anal	Pectoral	Pelvic	Upper	Lower

 - Internally at base of hindbrain
- Gut: Dorsal and ventral surface
- Body: Concentrated dorsally and ventrally
- Caudal: "Fleshy caudal extension" is distinctly pigmented; pigment is scattered evenly dorsally and ventrally on body and into finfolds

Diagnostic characters

- Morphology: Elongate form, gut length (40% SL)
- Number of myomeres (>225)
- Pigment pattern: Concentrated ventrolateral spots and pigment on fleshy caudal extension

^aKobayashi (1961b) reports slightly different meristics in specimens from Japanese waters:

Dorsal fin spines	79-83
Dorsal fin rays	141-157
Anal fin rays	166-193
Pectoral fin rays	11-13
Branchiostegal rays	6

Richardson and Dehart (1975) note that in four larval specimens collected off Oregon the total vertebral counts of 227 were considerably lower than counts in Bering Sea specimens (236-240).

^bLarvae 20.3-36.0 mm SL collected March-May 18 km from coast of Oregon.

Ref: Richardson and Dehart 1975.

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	3.5 mm
No. of oil globules	One
Oil globule diameter	
Yolk	
Envelope	
Hatch size	13 mm SL (preserved)
Incubation time/temp.	~1 yr
Pigment	

Diagnostic characters

- Precocious caudal development

LARVAE

Preanal length	35-40% SL, increases with development
Length at flexion	Occurs prior to hatch
Length at transformation	
Sequence of fin development	Caudal, dorsal and anal, pectorals and pelvics
Pigment	

- On about every other myomere along ventral midline
- Distinct spots on hypural margin, increase in number with development to become a line
- Large melanophores cover entire surface of gut
- Several large melanophores on crown
- Anterior dorsal midline starts on nape, increases posteriorly

Diagnostic characters

- Early caudal development
- Hypural margin pigment: First forms line, then an anteriorly open bracket; similar smaller bracket develops on the caudal peduncle
- Slightly separate dorsal fins
- Anal fin longer than second dorsal fin

To distinguish from *Arctoscopus japonicus* (present in the Bering Sea)^b

- *A. japonicus* larvae are less advanced at similar stages of development than those of *T. trichodon*, e.g., newly hatched *A. japonicus* larvae possess no developing fin rays and an unflexed notochord
- Dorsal margin pigment not present until juvenile stage in *A. japonicus*
- *A. japonicus*: Dorsal X-XI,13; anal 30-31

Figures A–D, Marliave 1981b.

Clinids are found in both Atlantic and Pacific tropical and temperate waters. They are small (many <7.5 cm) and elongate, and somewhat deep-bodied. The dorsal fin extends from behind the head almost to the caudal fin. In the northeastern Pacific the family is represented by only three species in two genera. Adults inhabit nearshore rocky areas from intertidal zones to depths of 50 m. Spawning behavior consists of nest building by a male in a rocky crevice, on seaweed, or in the lumen of a living sponge (Breder and Rosen 1966). Eggs, which are laid by one or more females, form clumps. The adhesive eggs (0.85-1.7 mm) have one or more oil globules which may be uncolored, pale yellow, or orange; sticky filaments are present on eggs of some species. Males of some tribes possess a modified anal fin or intromittent organ (Ophiclini, Clinini), and reproduction within those tribes is either viviparous or ovoviviparous. Larvae are pelagic for a brief period before settling to the bottom (Breder and Rosen 1966). The early-life-history stages of *Heterostichus rostratus* are presented here. Other clinids in the study area include two species of the genus *Gibbonsia*. In comparison to *H. rostratus*, members of *Gibbonsia* have fewer myomeres (48-54), anal fin rays (23-29), pectoral fin rays (11-13), and upper gill rakers (3-4). They undergo flexion and transformation earlier than *H. rostratus* (5.0-8.1 mm SL and ~19 mm SL, respectively).¹ Pigment is generally limited to the ventral midline and dorsally over the swimbladder.

Gobiidae is the most speciose family of marine fishes, although some species occur in brackish or freshwater environments. Gobies are generally small bottom-dwelling fishes with pelvic fins united to form a sucking disc. Found mainly in subtropical and tropical areas, adults inhabit shallow to moderate depths in salt and brackish water (some in freshwater). The study area includes three species: *Clevelandia ios*, *Coryphopterus nicholsi*, and *Lepidogobius lepidus*. Larvae are easily recognized by their conspicuously pigmented swimbladder and pigment patterns. Larvae are commonly collected inshore and in bays and estuaries. They are rare in coastal ichthyoplankton collections in the study area.

Small larvae of *Clevelandia* and *Lepidogobius* have been confused for some time in the literature. Since we have incomplete developmental series of the two species, we are presenting a consensus of opinion from researchers who have had more experience studying or collecting gobies. Gobiid larvae with three dorsal melanophores previously assigned to *Clevelandia* are now considered *Lepidogobius* (Wang 1986; W. Watson and G. McGowen, pers. commun.¹).

- Total myomeres (fewer in *C. nicholsi*, 25-26 vs. 37-38)

Figures A–B, NWAFC originals (B. Vinter; specimens loaned by Bruce Mundy, formerly of Oregon State University, for illustration).

There are four species of cutlassfishes in three genera of this family in the northeastern Pacific. General body shape is elongate and ribbonlike, tapering to a small caudal fin. Voracious predators, most have a large, well-toothed mouth and pointed snout. Adult cutlassfishes are benthopelagic but have been found at the surface at night (Fritzsche 1978). Spawning occurs offshore, resulting in pelagic eggs which can be 1.6-2.5 mm and have a single reddish-yellow oil globule (Breder and Rosen 1966, Fritzsche 1978). Pelagic larvae have a high myomere count (generally >100) and develop three dorsal spines, the first of which may be elongate (Schmidt and Strubberg 1918). Larvae have a small head with a long, tapering body (Ozawa 1986e). No early-life-history stages have been collected in our area.

EARLY LIFE HISTORY DESCRIPTION

EGGS - Family

Diameter	1.7-2.0 mm
No. of oil globules	
Oil globule diameter	
Yolk	
Envelope	
Hatch size	4.5-6.5 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

LARVAE^b

Preanal length	
Length at flexion	
Length at transformation	
Sequence of fin development	Dorsal first fin to develop
Pigment	
	<ul style="list-style-type: none"> • Blotch on upper preopercle • Crown • Dorsal midline beginning just anterior to dorsal fin origin and running along developing fin, increasing with development • Dorsolateral gut • Ventrolateral blotch about mid-postanal body; with development becoming a series along ventral midline about 3/4 length of anal fin • <i>B. elongatus pacificus</i> has a blotch at the origin of the anal fin (not shown on figure)^c

Diagnostic characters

- Family
 - Serrate spines in dorsal, anal, and pelvic fins
 - In some genera (e.g., *Benthodesmus*), the anterior-most rays of the dorsal fin are extremely elongate in the smallest larvae
- Genus
 - Caudal fin development distinct
 - Pelvic fin located approximately below pectoral fin
 - Number of dorsal fin spines (>30)

BENTHODESMUS

Figure A, Collette et al. 1984b (Gulf of Mexico specimen); B, Gorbunova 1982b; C, Evseenko 1982 (B–C, redrawn; subspecies from North Atlantic).

Spawning	Season: Apr-July (California) ^b Area: 0-72 m, 3-32 km from shore ^c Mode: Migration:
Fecundity	Range/function: >1 million (may spawn more than once each year) ^b
Age at first maturity	2 yr ^b -6 yr ^d
Longevity	10 yr ^b ; 12 yr ^e

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	0.9-1.3 mm
No. of oil globules	One, ventral
Oil globule diameter	0.26 mm
Yolk	Homogeneous
Envelope	Smooth, clear
Hatch size	3.3 mm SL
Incubation time/temp.	
Pigment	
• Oil globule	
• Yolk	

Diagnostic characters

- Posterior position of oil globule

LARVAE

Preanal length	52%, increasing with development to 64% SL
Length at flexion	6 mm SL
Length at transformation	15 mm SL
Sequence of fin development	2nd dorsal (rays) and anal, 1st dorsal (spines), pectorals and pelvics

Pigment

- Pigment on crown extends anteriorly with development
- Dorsolaterally on gut
- Ventral midline
- Postflexion
 - Short dorsal midline series develops under dorsal fin, spreading anteriorly
 - Ventral midline becomes restricted to posterior half of body
 - Mediolateral pigment

Diagnostic characters

- Large head with teeth
- Myomeres (30-31)
- Pigment pattern

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	
No. of oil globules	
Oil globule diameter	
Yolk	
Envelope	
Hatch size	<3.5 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters**LARVAE**

Preanal length	~60% SL, decreasing with development
Length at flexion	
Length at transformation	
Sequence of fin development	Pelvics and anterior dorsal fin spines form early
Pigment^c	<ul style="list-style-type: none"> • Few spots on upper jaw • With development above urostyle • Lightly on caudal fin, hypural region with several spots • Gut • With development on pectoral fin rays

Diagnostic characters

- Morphology
 - Deep-bodied but not as kite-shaped as acanthurids
 - Large square-shaped head with small terminal mouth
 - Extensive head spination
 - With development, minute spines on soft rays and along body surface
 - Dorsal and pelvic spines elongate, finely serrated
 - Loss of meristic elements with growth
- Not shown on figure^d
 - Spines on ascending process of premaxillary bone (important feature uniquely shared with *Zanclus canescens*, a closely related acanthuroid, and acanthurids)
 - Small dorsal spine anterior to first dorsal spine appears later in development

Figures A–D, Nishikawa 1987 (western Pacific specimen).

ELH pattern	Oviparous, pelagic eggs, pelagic larvae
Spawning	Season: Area: Mode: Migration:
Fecundity	Range/function:
Age at first maturity	
Longevity	

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	1.52-1.80 mm
No. of oil globules	One
Oil globule diameter	0.30-0.44 mm (large)
Yolk	Homogeneous
Envelope	Clear, smooth
Hatch size	
Incubation time/temp.	
Pigment	<ul style="list-style-type: none"> • Dorsal pigment along body • Ventral pigment from head to tip of tail • Underside of oil globule becomes pigmented with development

Diagnostic characters**LARVAE**

Preanal length	50-58% SL
Length at flexion	~9.3-11.0 mm SL
Length at transformation	~20 mm SL
Sequence of fin development	Caudal, 2nd dorsal (rays), anal, pectorals, 1st dorsal (spines), pelvics

Pigment

- Dorsal and ventral body midline pigment
- Lateral line dashes develop during flexion
- Head and tail pigment increases with development
- Become heavily, uniformly pigmented including fin membranes

Diagnostic characters

- Distinguished from *Tetragonurus cuvieri* (p. 560) by
- High myomere counts (56-62)
 - Preflexion: Dorsal body pigment over posterior half of body; only on tail in *T. cuvieri*
 - Flexion: No preopercular spines
 - Postflexion
 - Dorsal and anal spines weak, few (three) dorsal spines
 - More dorsal and anal fin rays than in *T. cuvieri*

^aNumber of preanal myomeres appears to decrease with development (B. Sumida, NMFS Southwest Fish. Cent., P.O. Box 271, La Jolla, CA 92038, pers. commun., 16 Dec. 1986).

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	1.10-1.28 mm
No. of oil globules	One
Oil globule diameter	0.25-0.30 mm (amorphous)
Yolk	Homogeneous
Envelope	Smooth, golden
Hatch size	4.0-4.1 mm SL
Incubation time/temp.	
Pigment	

- Oil globule
- Distinctive pigment on embryo; double dorsal line separating prior to head, outlining brain, and extending forward to snout
- Ventral pigment above digestive tract, continuing along tail

Diagnostic characters

- Pigment

LARVAE

Preanal length	60-70% SL
Length at flexion	7.6-10.1 mm SL
Length at transformation	~21.4 mm SL
Sequence of fin development	Caudal; 2nd dorsal (rays), anal, and pectorals; 1st dorsal (spines); pelvics

Pigment

- Tail
- Lateral line notable during flexion
- Eye bar
- Dorsal midline on caudal peduncle extending anteriorly with development

Diagnostic characters

- Distinguished from *Icichthys lockingtoni* (p. 558) by
- Myomere count (52-57)
 - Pigment
 - Notochord tip and base of caudal
 - Ventral row over gut to tail
 - Early formation of opposing 2nd dorsal and anal fins
 - Slender body with long caudal peduncle

^aNumber of preanal myomeres appears to decrease with development (B. Sumida, NMFS Southwest Fish. Cent., P.O. Box 271, La Jolla, CA 92038, pers. commun., 16 Dec. 1986).

Pleuronectiformes

Pleuronectiforms are benthic fishes that are asymmetrical with both eyes on one side of the head. Asymmetry is also reflected in dentition, cranial osteology, pelvic fin placement and morphology, pigment, and squamation. Worldwide in distribution, there are 7 families, with well over 120 genera and 500 species (Ahlstrom et al. 1984a). Most families are defined as dextral (eyes on right side) or sinistral (eyes on left side), although some species are indiscriminate. A total of 3 families with 31 species occur in the study area. Much is known about the early life history of many species. Eggs of most are pelagic, spherical, and have homogeneous yolks. Chorions may be smooth, striated, or ornamented with raised polygonal patterns (Ahlstrom et al. 1984a). Early larvae are bilaterally symmetrical and swim upright. Of help in larval identification are body shape (short gut, elongate body), pigment patterns (postanal bands, pigment on the urostyle and finfolds), and meristic characters. Size at transformation and the development of spines and elongate dorsal or pelvic fin rays can be diagnostic. During transformation, the eyes migrate to their adult position and the larvae assume the distinctive flat profile unique to the order. At this point, juveniles settle and become benthic inhabitants.

Families in study area: **Paralichthyidae**
Pleuronectidae
Cynoglossidae

Table 49
Characters useful in identifying pleuronectiform larvae. Size data are after Ahlstrom et al. (1984a), in part.
All measurements are in millimeters NL or SL. Taxa listed alphabetically within families.

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	0.55-0.77 mm; ^c 0.51-0.79 mm ^d
No. of oil globules	One
Oil globule diameter	0.09-0.12 mm
Yolk	Homogeneous
Envelope	Smooth
Hatch size	~2.0 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

We cannot identify *Citharichthys* spp. eggs to species. We collect two types of paralichthyid eggs: the first type has an average diameter of ~0.64-0.68 mm, and the other type averages ~0.78-0.88 mm.

LARVAE^e

Preanal length	<50% SL
Length at flexion	<10.0-11.4 mm SL
Length at transformation	20->39 mm SL
Sequence of fin development	Dorsal, anal, caudal, pelvics, pectorals <u>or</u> caudal, dorsal and anal, pelvics, pectorals

Pigment

- Ventral body midline pigment posterior to anus, coalesces later into two melanophores
- Band at 3/4 BL
- Posteriorly on gut
- Tips of elongate dorsal and pelvic fin rays

Diagnostic characters

- Elongate dorsal and pelvic fin rays

^a 11 branched rays.

^b Smith 1936

^c Arora 1951

^d Ahlstrom et al. 1984a

^e Early preflexion larvae (<6-7 mm SL) of *C. sordidus* and *C. stigmaeus* are not identifiable to species until the elongate dorsal fin rays form on *C. sordidus* (~7 mm SL). Preflexion larvae collected in our study area do not resemble the published illustrations of either species (Ahlstrom and Moser 1975); they have ventral gut pigment extending more anteriorly, a series of postanal ventral midline melanophores, no finfold pigment, and less intense caudal pigment (Fig. A). Specimens >6.9 mm SL that have elongated dorsal fin rays are *C. sordidus* (Fig. B), but do not exhibit the intense caudal pigment shown by Ahlstrom and Moser (1975). Our specimens indicate a decrease in intensity of caudal pigment with development for *C. sordidus* and an increase for *C. stigmaeus*. The preflexion larva of *C. sordidus* illustrated by Ahlstrom and Moser (1975) may belong to another species probably south of our study area, most likely *C. xanthostigma* (B. Sumida, NMFS Southwest Fish. Cent., Box 271, La Jolla, CA 92038, pers. commun., 16 Dec. 1986).

Diagnostic characters

See notes on *C. sordidus* (p. 568)

LARVAE

Preanal length	
Length at flexion	9.2-10.2 mm SL
Length at transformation	24.0-35.5 mm SL
Sequence of fin development	Dorsal, anal, caudal, pelvics, pectorals <u>or</u> caudal, dorsal and anal, pelvics, pectorals

Pigment (see *C. sordidus*)

- Urostyle pigment increases in intensity to flexion stage, then fades
- Small melanophores along ventral body midline posterior to anus; these migrate onto anal fin pterygiophores in postflexion larvae
- Band at 3/4 BL, lost after flexion
- Caudal fin

Diagnostic characters

- Lack of elongate fin rays

^a 11 branched rays.

^b Ahlstrom and Moser 1975

Ref: Ahlstrom et al. 1984a.

Figures A–B, Ahlstrom and Moser 1975.

The majority of species in the order (27 out of a total of 31) belong to the family Pleuronectidae. Ahlstrom et al. (1984a) summarize the following ontogenetic characters for the family.

Egg size ranges from 0.66 to 4.50 mm, yolk is homogeneous, oil globules are absent in most species, and the chorion is smooth (exceptions include *Pleuronichthys ritteri* and *P. cornutus*). Some light sculpturing of the chorion is seen in several species.

Larvae hatch from 1.7 to 16.0 mm SL. They possess no elongate dorsal or pelvic fin rays, gut is normal, and spines are limited to the preopercular, otic, and frontal regions, although absent in most.

The caudal fin ray count is not stabilized within pleuronectids, in contrast to most other taxa. Most pleuronectids have 17-19 total caudal fin rays (18 is most common). Within species there is variability in the total fin ray count and in the number of rays that are branched. Since variability exists, total counts, number of branched rays, and principal and secondary rays are given when available.

Table 50
Pigment characters and myomere counts that may be useful in the identification of pleuronectid larvae during the preflexion and early flexion stages.*

Genus	Pigment characters					Total myomeres
	Number of bands	Slashlike hypaxial pigment	Urostyle	Finfold

Diagnostic characters

LARVAE

Preanal length	<50% SL
Length at flexion	8.4-9.9 mm SL
Length at transformation	~20-24 mm SL
Sequence of fin development	Caudal, dorsal and anal, pelvics, pectorals

Pigment

- Series of ventral midline melanophores extending around urostyle
- Several spots above notochord, number increases with development
- During flexion, pigment develops along hypaxial myomeres
- Initially, gut pigment restricted to dorsal and anteroventral surface; with development it extends posterodorsally and along ventral surface

Diagnostic characters

- Pigment
 - Pigment pattern without bands
 - Presence of hypaxial pigment
 - Presence of pigment around urostyle

^a 17 branched rays.

^b Richardson 1981b

^c According to Figures C and E from Richardson (1981b), flexion occurs rapidly between 15.4 and 16.2 mm SL. However, the 18.5-mm NL specimen (Fig. D) illustrated by Ahlstrom et al. (1984a) does not appear fully flexed. Differences in size may be a result of preservation.

Ref: Ahlstrom et al. 1984a, Richardson 1981b.

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	2.8-3.1 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Homogeneous
Envelope	Smooth
Hatch size	~9 mm SL
Incubation time/temp.	
Pigment	
	• Eye
	• Hindgut extending out into yolk
	• Three postanal bands

Diagnostic characters

- Size
- Pigment pattern

LARVAE

Preanal length	40% SL
Length at flexion	15.4-16.2 mm SL ^c
Length at transformation	>16.2 mm SL when eye migration commences
Sequence of fin development	Caudal, dorsal, and anal; pelvics; pectorals

Pigment

- Initially, three postanal bands with pigment on the finfold in region of bands; number of dorsal and ventral spots change with size and stage of development
- Pigmentation increases with development along finfold margin (~7 spots along dorsal and 5 spots along anal in flexion larvae)

Diagnostic characters

- Postanal band pattern in preflexion larvae (three bands)
 - High myomere count (57-65)
- Distinguished from similar larvae with high myomere count by
- Presence of three postanal pigment bands and median finfold pigment
 - Reinhardtius hippoglossoides* (p. 622): Lightly pigmented and without bands
 - Glyptocephalus* spp. (p. 584, 586): Three bands (more laterally intense) in *G. stelleri*; in *G. zachirus*, caudal band, no finfold pigment
 - Unidentified ophidiid larvae (p. 213): More myomeres (>75), less finfold pigment, and less pronounced loop in gut

Figures A–C, E, Richardson 1981b; D, Ahlstrom et al. 1984a.

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	0.84-1.00 mm; occasionally up to 1.10 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Homogeneous
Envelope	Striated
Hatch size	2.7-2.9 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

Very difficult to distinguish from the three other 1.0-mm pleuronectid eggs in the area:

- Parophrys vetulus* (p. 610)
- Platichthys stellatus* (p. 612)
- Psettichthys melanostictus* (p. 620)

LARVAE

Preanal length	<50% SL
Length at flexion	9-10 to 14 mm SL
Length at transformation	15->21 mm SL
Sequence of fin development	Caudal, dorsal, and anal; pelvics; pectorals
Pigment	<ul style="list-style-type: none"> • Three postanal bands at 50, 67, 90% SL • Melanophores extend ventrally on gut and along posterior portion of abdominal cavity

Diagnostic characters

- Three pigment bands
- Low myomere count (41-42)

^a 11 branched rays.

Longevity	15 yr (females) ^f 22 yr (males) ^f

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	0.87-1.00 mm; 1.02-1.09 mm ^g
No. of oil globules	None
Oil globule diameter	
Yolk	Homogeneous
Envelope	Thick, elastic, bright yellow or orange
Hatch size	5 mm SL; 3.6-4.0 mm SL; ^g 3.4-3.8 mm SL ^h
Incubation time/temp.	9-12 d/6.5-8.0°C
Pigment	

Diagnostic characters

- Demersal egg

LARVAE

Preanal length	<50% SL
Length at flexion	8.4-9.9 mm SL
Length at transformation	~20 mm SL; >17.7 mm SL ^h
Sequence of fin development	Caudal, dorsal, and anal; pelvics; pectorals
Pigment	

- Dorsally on peritoneum, ventrolateral gut pigment becoming posterolateral with development
- Postanal ventral melanophores ~3/4 length of body
- Two dorsolateral patches, the posterior one becoming a band meeting the ventral surface
- Anal finfold lightly pigmented on posterior half

Diagnostic characters

- Distinguished from other pleuronectids by
- Presence of one band posteriorly on body, not as conspicuous as most
 - Size at transformation (20 mm SL)
 - Advanced stage of development at hatching

See *Lepidopsetta* 2 (p. 599) and *Psettichthys melanostictus* (p. 620)

Figure A, Pertseva-Ostroumova 1961; B-E, NWAFC originals (B. Vinter).

Lepidopsetta bilineata/*Lepidopsetta 2*/*Psettichthys melanostictus*

Two readily distinguishable types of *Lepidopsetta* larvae are collected in our study area which we designate *Lepidopsetta bilineata* and *Lepidopsetta 2*. Wilimovsky et al. (1967) had previously indicated that there are two subspecies of *Lepidopsetta* in the Northeast Pacific based on adult specimens (*L. b. bilineata* and *L. b. peracuata*). *Lepidopsetta 2* larvae are very similar to larvae of *Psettichthys melanostictus* at certain stages of development. We present *Lepidopsetta 2* as a separate series, since these larvae are distinct from those of *L. bilineata* and *P. melanostictus*. The following pigment patterns and morphological characters separate the three kinds of larvae.

Psettichthys melanostictus (see also p. 620)

Range from California to Alaska, but the center of distribution appears to be off California, Oregon, and Washington.

Pigment

- Postanal ventral midline melanophores: Usually restricted to 3-4 large spots
- Tail pigment less prominent than on *Lepidopsetta 2*
- Pigment on upper and lower jaw
- Isthmus pigment heavier than on others
- First spot along dorsal midline more anterior (over anus)

Morphology

- Gut coiled, shape of posterior gut
- Deeper body (wider finfold)

Lepidopsetta 2 (see p. 600, 601)

Range from Puget Sound to Alaska, and center of distribution appears to be off Southeast Alaska and in the Gulf of Alaska.

Pigment

- Postanal ventral midline melanophores: A series of small melanophores extending from the gut to the last myomere; sometimes a larger spot occurs about midbody (with larvae 6.3-9.7 mm SL, there may be more spots than at other sizes)
- First spot along dorsal midline behind anus
- Other: Tail pigment more intense, but mouth and isthmus pigment less intense than on *Psettichthys*

Morphology

- Eye relatively larger than on *Psettichthys* at similar ontogenetic stages
- Gut shape simple

Lepidopsetta bilineata (see also p. 596)

Range from southern California to the Bering Sea.

Pigment

- Postanal ventral midline melanophores: A series of small melanophores extending from the gut to about 2/3 body
- Only two spots along dorsal midline; anterior spot at midbody, posterior spot forming a band at about myomere 30
- No heavy pigment along edges of median finfold
- Tail pigment less prominent than on others
- Pigment along hypural edge

Morphology

- Gut shape simple

Finfold pigment may or may not be an additional criterion for separating *Lepidopsetta 2* and *Psettichthys*. Many *Psettichthys* specimens in our collection appear to have more prominent finfold pigment that is retained longer during development; however, many of these are laboratory-reared specimens. More wild-caught *Psettichthys* specimens are needed to verify whether they all have intense finfold pigment.

Yolksac larvae are more difficult to separate. *Psettichthys* larvae appear to possess upper and lower jaw pigment, smaller, more concentrated melanophores in the finfold and on the urostyle, and the last postanal band has a ventral stripe only. *Lepidopsetta 2* yolksac larvae appear to have only lower jaw pigment, larger, fewer, and evenly spaced melanophores in the finfold and urostyle, and the last postanal band has a dorsal and ventral stripe.

Literature: Specimens illustrated by Ahlstrom et al. (1984a) are both *Psettichthys* based primarily on the presence of the coiled gut and the 2-3 large ventral melanophores (Fig. 351C, p. 662, and Fig. 352E, p. 663). Hickman (1959) illustrated six *Psettichthys* larvae from specimens he reared from eggs (his Figs. 1 and 2) and from specimens he collected in Puget Sound (his Figs. 3-6). Hickman's Figures 3 and 4 appear to resemble *Lepidopsetta 2* larvae, while his other figures appear to resemble *Psettichthys*.

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	0.76-0.85 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Homogeneous, yellowish
Envelope	Clear, smooth
Hatch size	2.25-2.80 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

- Size

LARVAE

Preanal length	<50% SL
Length at flexion	~7 mm SL; 7.5-9.5 mm SL ^c
Length at transformation	15-17 mm SL; may begin at 10 mm SL ^c
Sequence of fin development	Caudal, dorsal and anal, pelvics, pectorals
Pigment	

- Mediolateral, along notochord
- Ventrolateral, along hypaxial myomeres
- Anal finfold

Diagnostic characters

- Distinguished from other pleuronectids without postanal pigment bands by
- Ventrolateral pigment along hypaxial myomeres
 - Size at transformation (15-17 mm SL)
 - Finfold pigment restricted to anal fin
 - Urostyle unpigmented

L. proboscidea and *L. sakhalinensis*^d eggs and larvae are incompletely known. The following information may aid in identification.

	<i>L. proboscidea</i>	<i>L. sakhalinensis</i>
Egg diameter	0.72-0.87 mm	
Total vertebrae	38-40

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	1.47-1.71 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Homogeneous
Envelope	Surface may be irregular and appear bumpy
Hatch size	~5.6 mm SL
Incubation time/temp.	
Pigment	
	• Yolksac
	• Late-stage embryo: Distinct caudal pigment visible

Diagnostic characters

- Caudal pigment
- Smallest size range of three similar-looking pleuronectid eggs in the 1.5-2.5 mm size range; see *Glyptocephalus zachirus* (p. 586) and *Microstomus pacificus* (p. 608)

LARVAE

Preanal length	<50% SL
Length at flexion	9.0-10.9 mm SL
Length at transformation	15.7-24.7 mm SL
Sequence of fin development	Caudal, dorsal and anal, pelvics, pectorals

Pigment

- Early and midflexion larvae
 - Dorsal and ventral midline melanophores around tail and in finfold; with development, these melanophores move laterally on body along myoseptal lines
 - Finfold pigment increases to cover anal finfold and posterior half of dorsal finfold
- Gut pigment increases ventrally with development

Diagnostic characters

- Distinguished from other pleuronectids without pigment bands by
- Pigment pattern: Continuous dorsal and ventral midline
 - In preflexion larvae, the anterior melanophores of the dorsal midline series extend laterally
 - Finfold pigment

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	2.05-2.68 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Homogeneous
Envelope	Smooth, slightly thick
Hatch size	~6 mm SL
Incubation time/temp.	27 d/10°C
Pigment	
• Yolksac	
• Late-stage embryo: Caudal pigment not as pronounced as <i>Lyopsetta exilis</i> (p. 606)	

Diagnostic characters

- Largest egg of three similar-looking pleuronectid eggs; see *L. exilis* and *Glyptocephalus zachirus* (p. 586)

LARVAE

Preanal length	<50% SL
Length at flexion	10-15 mm SL
Length at transformation	Eye migration begins at 20 mm SL; larvae remain pelagic >45 mm SL
Sequence of fin development	Caudal, dorsal and anal, pelvics, pectorals
Pigment	

- Lower jaw; dorsally and ventrally on gut, with development becoming restricted to ventral surface (isthmus to anus)
- Preflexion
 - Three pigment patches in addition to tail and finfold
 - Anterior patch restricted to ventral area; two posterior patches have dorsal and ventral components extending into finfold
 - Around urostyle and in finfold
- Flexion: Pigment patches occur above notochord and along distal ends of finfold
- Postflexion: Pigment patches along dorsal and anal pterygiophores

Diagnostic characters

- Distinguished from other pleuronectids with 3-4 pigment bands by
- Pigment bands extending into finfold
 - Morphology: Early larvae long and slender, becoming deep-bodied during development
 - Otic spines
 - Myomeres (50-55)

See also *G. zachirus* (p. 586) and *Hippoglossoides elassodon* (p. 588)

EARLY LIFE HISTORY DESCRIPTION

EGGS

Diameter	0.80-1.05 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Homogeneous
Envelope	Thin, smooth, transparent
Hatch size	2.3-2.8 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

- See *Isopsetta isolepis* (p. 594)

LARVAE

Preanal length	43-45% SL
Length at flexion	~10 mm SL; 8.8-10.5 mm SL ^g
Length at transformation	Eye migration prior to 17.5 mm SL
Sequence of fin development	Caudal, dorsal and anal, pelvics, pectorals
Pigment	

- Initially, anteroventrally on gut; with development, extending posteriorly; in postflexion, a line of pigment forms along the posterior hindgut and anus
- Dorsal and ventral midline: Ventral beginning prior to anus (~ myomere 5) and dorsal at ~ myomere 15 (pigment is variable); dorsal midline becoming less prominent with development as internal pigment develops above notochord through flexion stage
- Myoseptal pigment develops along hypaxial myomeres in postflexion larvae
- Finfold pigment restricted to anal finfold

Diagnostic characters

- Distinguished from other pleuronectids without pigment bands by
- Dorsal and ventral midline pigment, hypaxial pigment
 - Finfold pigment restricted to anal finfold

Note: The number of dorsal midline melanophores in preflexion larvae is highly variable.

Figures A–B, D, NWAFC originals (B. Vinter); C, Ahlstrom et al. 1984a (after Ahlstrom and Moser 1975).

LARVAE

Preanal length	<50% SL
Length at flexion	~7 mm SL; 5.5-6.0 mm SL ^e
Length at transformation	10.5 mm SL (may be slightly smaller, 8-9 mm SL)
Sequence of fin development	Caudal, dorsal and anal, pelvics, pectorals

Pigment

- Lightly scattered over head and posteroventrally along gut
- Initially, in preflexion larvae, postanal pigment scattered along anal finfold and along posterior 1/3 of body
- Around urostyle
- Internally above notochord, becoming less concentrated with development
- Pigment in dorsal fin disappears with development
- Postflexion larvae lightly pigmented with lateral patches

Diagnostic characters

- Distinguished from other pleuronectids without pigment bands by
- Lack of dorsal midline pigment
 - Small size at transformation (<10 mm SL)

Oil globule diameter	
Yolk	Homogeneous
Envelope	Sculptured with polygonal pattern
Hatch size	3.9 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

- Egg diameter (1.20-1.56 mm)
- Polygonal sculpturing on envelope surface

LARVAE

Preanal length	<50% SL
Length at flexion	6.2-8.5 mm NL
Length at transformation	8.2->11.4 mm SL
Sequence of fin development	Caudal slightly before dorsal and anal, pectorals

Pigment

- Preflexion larvae: Opposing pigment clusters on dorsal and ventral finfolds, increasing with development
- Small melanophores covering all but posterior 1/4 of body

Diagnostic characters (see Table 3)

- Distinguished from other pleuronectids without pigment bands by
- Heavy pigment pattern
- Distinguished from *P. decurrens* by
- Pigment pattern: *P. coenosus* has less finfold pigment than *P. decurrens*
 - Precaudal vertebrae 12-13, whereas *P. decurrens* usually has 14-15
 - Lack of pterotic spines

Note: Preflexion larvae occasionally have more snout and lower jaw pigment than shown on figure.

Figure A, Budd 1940; B-E, Sumida et al. 1979.

MERISTICS

Vertebrae	Total: 38-39-41 Precaudal: 13-14-15 Caudal: 24-25-26
Branchiostegal rays	7-X-8
Caudal fin	2, 7+7, 2 Total rays = 19 ^a
Pelvic fin	Thoracic R: 4-6-7
Dorsal fin	R: 67-75-81
Pectoral fin	R: 9-12-14
Anal fin	R: 45-50-55
Gill rakers	U: 3-X-4 L: 6-X-9

LIFE HISTORY

Range	South of southern California to Bering Sea, 54-66°N
Ecology	Epi-, meso-, and bathybenthal, 8-532 m
ELH pattern	Oviparous, pelagic eggs, pelagic larvae
Spawning	Season: Area: Mode: Migration:
Fecundity	Range/function:
Age at first maturity	
Longevity	

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	1.84-2.08 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Homogeneous
Envelope	Sculptured with polygonal pattern
Hatch size	4.9-5.5 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

- Egg diameter (1.84-2.08 mm)
- Polygonal sculpturing on envelope surface

LARVAE

Preanal length	~50% SL
Length at flexion	7.8-11.0 mm NL
Length at transformation	10.5->21.0 mm SL ^b
Sequence of fin development	Caudal slightly before dorsal and anal, pectorals

Pigment

- Nearly entire body and finfolds pigmented except posteriorly in preflexion larvae; banding pattern develops in postflexion larvae

Diagnostic characters (see Table 3)

- Distinguished from other pleuronectids without pigment bands by
- Heavy pigment pattern
 - Pterotic spines
- Distinguished from *P. coenosus* by
- See *P. coenosus* (p. 616)
 - In addition to having pterotic spines, more pigment, and more precaudal myomeres, *P. decurrens* is larger at various stages of development (see figures).

^a12 branched rays.^bEye migration by 10 mm SL, but not complete in some until >21 mm SL.

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	0.83-1.04 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Clear
Envelope	
Hatch size	<3 mm SL
Incubation time/temp.	
Pigment	<ul style="list-style-type: none"> • Yolksac: May appear as early as late middle stage

Diagnostic characters

See *Isopsetta isolepis* (p. 594); usually pigment on yolksac and in later stages on finfold

LARVAE (see discussion, p. 599)

Preanal length	<50% SL
Length at flexion	~8-10 mm SL
Length at transformation	>22.6 mm SL
Sequence of fin development	Caudal, dorsal and anal, pelvics, pectorals
Pigment	<ul style="list-style-type: none"> • Postanal body <ul style="list-style-type: none"> —3-4 large spots along ventral midline —Three spots along dorsal midline; the first spot more anteriorly placed than the first ventral spot • Prominent pigment along edges of dorsal and ventral finfolds • Mouth, isthmus • Gut pigmented along ventral midline and posterior edge

Diagnostic characters

See *Lepidopsetta bilineata* (p. 596) and *Lepidopsetta 2* (p. 599)

Distinguished from other pleuronectids with pigment bands by

- Distinctive pigment along edges of dorsal and ventral finfolds and dorsal and ventral body midlines

Figures A–D, NWAFC originals (B. Vinter).

Pectoral fin	R: 11-14-15
Anal fin	R: 63-72-79
Gill rakers	U: 3-X-6 L: 11-X-16

LIFE HISTORY

Range	South of southern California to Chukchi Sea, north of 66°N
Ecology	Epi-, meso-, and bathybenthal, 14-2000 m
ELH pattern	Oviparous, pelagic eggs, pelagic larvae
Spawning	Season: Fall ^a Area: Continental slope (>100 m) ^a Mode: Migration:
Fecundity	Range/function: 15,000-215,000 (Atlantic)/ $F=0.000063 \times L^{4.66}$, $L=FL \text{ cm}^a$
Age at first maturity	13 (females, Okhotsk Sea) ^a
Longevity	>23 yr ^a

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	4.0-4.5 mm
No. of oil globules	None
Oil globule diameter	
Yolk	Homogeneous
Envelope	Smooth, transparent
Hatch size	10-16 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters**LARVAE**

Preanal length	<50% SL
Length at flexion	25-27 mm SL
Length at transformation	45-65 mm SL
Sequence of fin development	Caudal, dorsal and anal, pelvics, pectorals
Pigment	

- Ventrally and posterolaterally on gut
- Light ventrolateral pigment along body from above gut, some dorsal, along peduncle; also in finfold above and below tail (~posterior 1/3)
- Increase in pigmentation in postflexion specimens

Diagnostic characters

- Newly hatched larvae large and unpigmented (except for eye)
- Distinguished from other pleuronectids with >60 myomeres by
- No band pattern and overall lightly pigmented
 - Glyptocephalus zachirus* (p. 586): Four postanal bands with more lateral intensity
 - Embassichthys bathybius* (p. 580): Three postanal bands
- Distinguished from *Hippoglossus stenolepis* (p. 592) (both have large unpigmented yolk sac larvae) by
- Depth of collection (>200 m)
 - High myomere count (61-64)
 - Hatch size (10-16 mm SL)

^aDunn and Sample 1976

Ref: Ahlstrom et al. 1984a, Jensen 1935.

Figures A–F, Jensen 1935 (A–D, reversed; specimens collected from West Greenland waters).

MERISTICS

Vertebrae	Total: 50-51-52 Precaudal: 9-9-9 Caudal: 41-X-43
Branchiostegal rays	6-6-6
Caudal fin	Total rays = 12 ^a
Pelvic fin	Thoracic; 4 rays on eyed side, absent on blind side
Dorsal fin	R: 95-X-106
Pectoral fin	Present during larval period but lacking in juvenile and adult stages
Anal fin	R: 77-X-90
Gill rakers	U: X-X-X L: X-X-X

LIFE HISTORY

Range	South of southern California to Oregon, 42-46°N
Ecology	Nearshore shelf demersal, 1-201 m
ELH pattern	Oviparous, pelagic eggs, pelagic larvae
Spawning	Season: June-Sept ^b Area: Mode: Migration:
Fecundity	Range/function:
Age at first maturity	
Longevity	

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	0.71-0.78 mm
No. of oil globules	Multiple, 10-23
Oil globule diameter	
Yolk	Homogeneous
Envelope	Smooth, colored
Hatch size	1.9 mm SL
Incubation time/temp.	
Pigment	

Diagnostic characters

- Multiple oil globules

LARVAE

Preanal length	50% NL decreasing with development to 28% SL
Length at flexion	9.4-10.8 mm SL
Length at transformation	19.0-24.2 mm SL
Sequence of fin development	Anterior dorsal; caudal, dorsal, and anal; pelvics ^c (pectorals disappear at metamorphosis)

Pigment

- Small melanophores along dorsal midline, larger along ventral midline
- Single band posteriad on tail
- Large blotches at finfold margin, with development restricted to along the distal edges
- Head, gut, and swimbladder

Diagnostic characters

- Morphology: Large head and tapering body
- Gut mass trails posteriad
- Five exerted dorsal fin rays develop by 6.0 mm SL but they are no longer than other fin rays (in other species of *Symphurus*, elongate anterior dorsal fin rays persist)
- Pelvic fin on blind side begins disappearing at 18.0-22.0 mm SL^c

^a All rays on hypurals, all unbranched.

^b Fitch and Lavenberg 1975

^c E.H. Ahlstrom notes

Figure A, Matarese and Sandknop 1984; B–D, Ahlstrom et al. 1984a.

Tetraodontiformes

Although most fishes of the Tetraodontiformes are tropical and associated with the bottom, some are found in temperate zones and remain pelagic throughout their lifespans. The general body shape is rounded or boxlike and the body may be encased in a bony carapace or covered with sharp spines. Many species are able to inflate themselves with water or air. Eight families, 92 genera, and 329 species make up the order (J. Nelson 1984). Only one family, Molidae, is found in the Northeast Pacific. The most unusual of the tetraodontiforms, molids have no caudal fin and propel themselves with large dorsal and anal fins. Eggs are pelagic, 1.42-1.80 mm in diameter, and have multiple oil globules (Leis 1984). Larvae hatch with a functioning jaw, pigmented eyes, and a dermal sac enclosing the head and trunk. With development, body spines form and the tail atrophies. Molids may have a long prejuvenile stage marked by retention of spines and a shape unlike that of adults (Leis 1984).

Family in study area: **Molidae**

MERISTICS

Vertebrae	Total: 17-X-18 Precaudal: 8-X-9 Caudal: 8-9-9
Branchiostegal rays	6-6-6
Caudal fin	Absent
Pelvic fin	Absent
Dorsal fin	R: 15-X-18
Pectoral fin	R: 11-X-13
Anal fin	R: 14-X-18
Gill rakers	U: X-X-X L: X-X-X

LIFE HISTORY

Range	South of southern California to SE Alaska, 55-59°N
Ecology	Epipelagic
ELH pattern	Oviparous, pelagic eggs, pelagic larvae
Spawning	Season: Spring-summer ^a Area: Mode: Migration:
Fecundity	Range/function: 300 million ^b
Age at first maturity	
Longevity	

EARLY LIFE HISTORY DESCRIPTION**EGGS**

Diameter	
No. of oil globules	
Oil globule diameter	
Yolk	
Envelope	
Hatch size	<1.84 mm TL
Incubation time/temp.	Other members of family hatch in 7-8 days
Pigment	

Diagnostic characters - Family

- Pelagic, large (1.4-1.8 mm), and have multiple oil globules

Larvae

Preanal length	<50% SL increasing with development to >50% SL
Length at flexion	Does not occur
Length at transformation	Long ontogenetic stage between larvae and juveniles
Sequence of fin development	Pectorals and caudal, dorsal and anal
Pigment - Family	
	• Usually heavily pigmented over gut and dorsal surfaces

Diagnostic characters

- Morphology: Wide, deep body
- Body spines with a ventral keel (form soon after hatching)
- Tail in young is normal but soon atrophies and a true caudal never forms; notochord flexion does not take place, so the clavus (gradual thickening near the distal end) is not homologous with the caudal fin^c

Rastrinus scutigera 399
Reinhardtius 573, 622-623
Reinhardtius hippoglossoides 567, 580, 622, 623
Rhamplocottus 361-362, 366-367
Rhamplocottus richardsoni 20, 21, 363, 366, 367
Rhinoliparis attenuatus 475
Rhinoliparis barbulifer 470, 475, 480, 481
Rimicola muscarum 232, 233
Rondeletia loricata 256
 Rondeletiidae 19, 249, 256
Ronquilus jordani 4, 27, 496, 497
Sagamichthys abei 77
 Salmonidae 51
 Salmoniformes 18, 51-81
 Salmonoidei 18, 79-81
Sardinops sagax 44, 46, 47
Sarritor frenatus 456
Sarritor leptorhynchus 456
Sciaonius pedicellaris 217
 Sciaenidae 19, 483, 492-493
 Scomberesocidae 19, 235-237
Scomber japonicus 486, 492, 554, 555
 Scombridae 19, 483, 554-555
 Scombroidei 18, 551-555

Scopelarchidae 19, 125-127
Scopeloberyx 252, 253
Scopeloberyx robustus 253
Scopelogadus 252, 253
Scopelogadus bispinosus 253
 Scopelomorpha 125-179
Scopelosarus harryi 128, 129
Scorpaenichthys 362-362, 382-383
Scorpaenichthys marmoratus 20, 22, 382, 383, 406
 Scorpaenidae 19, 267-337
 Scorpaeniformes 18, 267-481
 Scorpaenoidei 18, 267-337
Sebastes 267-272, 273-280, 281, 282-287, 288-335
Sebastes aleutianus 269, 271, 273, 283, 288, 289
Sebastes alutus 269, 271, 273, 283
Sebastes auriculatus 269, 271, 273, 285, 290, 291, 296
Sebastes aurora 269, 271, 274, 287, 292, 293
Sebastes babcocki 269, 271, 274, 287, 294, 295
Sebastes borealis 269, 271
Sebastes brevispinis 3, 269, 271, 274, 285
Sebastes caurinus 3, 269, 271, 275, 284, 290, 296, 297
Sebastes chlorostictus 269, 271, 275, 287
Sebastes ciliatus 269, 271, 275
Sebastes crameri 269, 271, 275, 284, 298, 299
Sebastes diploproa 269, 271, 276, 283, 300, 301
Sebastes elongatus 269, 271, 276, 287, 302, 303
Sebastes emphaeus 269, 271, 286, 304, 305
Sebastes entomelas 269, 271, 276, 282, 306, 307
Sebastes flavidus 269, 271, 276, 282, 308, 309, 314
Sebastes glaucus 269, 271
Sebastes goodei 269, 271, 277, 284
Sebastes helvomaculatus 269, 271, 277, 287, 310, 311
Sebastes jordani 3, 269, 271, 277, 286, 312, 313
Sebastes maliger 269, 271, 277
Sebastes melanops 3, 269, 271, 277, 282, 308, 314, 315
Sebastes melanostictus 269, 271
Sebastes melanostomus 269-271, 277, 284, 316, 317
Sebastes miniatus 269, 271, 278, 282, 318, 319
Sebastes mystinus 269, 271, 278, 282, 320, 321
Sebastes nebulosus 269, 271
Sebastes nigrocinctus 269, 271, 284
Sebastes paucispinis 269, 271, 278, 283, 322, 323
Sebastes pinniger 269, 271, 278, 282, 324, 325
Sebastes polyspinis 3, 269, 271, 278, 286
Sebastes proriger 269, 271, 278, 285, 326, 327
Sebastes rastrelliger 269, 271, 285
Sebastes reedi 269, 271, 279, 284, 328, 329
Sebastes ruberrimus 269, 271, 279, 287
Sebastes rufus 3, 269, 271, 279, 286, 330, 331
Sebastes saxicola 269, 271, 279, 284, 332, 333
Sebastes variegatus 3, 269, 271, 280
Sebastes wilsoni 269, 271, 286
Sebastes zacentrus 3, 269, 271-272, 280, 285, 334, 335
 Sebastinae 268-335
 Sebastobinae 268, 336-337
Sebastolobus 268, 336-337
Sebastolobus alascanus 336, 337
Sebastolobus altivelis 336, 337
Sebastolobus macrochir 336
Sebastolobus spp. 254, 336, 337
Serrivomer jespersenii 33, 36, 37
 Serrivomeridae 19, 31-33, 36, 37
Sigmistes 361
Spectrunculus grandis 211-212, 213
Spectrunculus radcliffei 212
Spirinchus starksi 79
Spirinchus thaleichthys 79
Stelgistrum 361
Stellerina xyosterna 456, 457
Stenobranchius 146-147, 172-173
Stenobranchius leucopsarus 3, 146, 172, 173, 176
Stenobranchius nannochir 146, 172
Sternias 361
 Sternoptychidae 19, 83, 92-105
Sternoptyx 84, 86, 92, 102, 103
Sternoptyx diaphana 93, 102, 103
Sternoptyx pseudobscura 93, 102, 103
Sternoptyx spp. 102, 104
 Stichaeidae 19, 26, 27, 483, 500, 501, 502, 503, 504, 505, 507-519
 Stichaeinae 500-501, 507
 Stichaeini 496, 500, 501, 507
Stichaeus punctatus 496, 501, 507
Stlegicottus 361
 Stomiiformes 18, 83-84, 85, 86-123
 Stomioidei 107-123
 Stromateidae 19, 483, 562-563
 Stromateoidei 18, 558-563
Symbolophorus 147, 154-155
Symbolophorus californiensis 146, 154, 155
Symphurus atricauda 567, 624, 625
 Synaphobranchidae 19, 31-34, 35
Synchirus 361-362, 410-411
Synchirus gilli 4, 410, 411
 Syngnathidae 19, 261, 264, 265
Syngnathus leptorhynchus 264
 Synodontidae 19, 125, 132-133
Synodus lucioceps 132, 133
Taaningichthys 146-147, 174, 175
Taaningichthys bathyphilus 146, 174-175
Tactostoma 106, 116-117
Tactostoma macropus 3, 106, 116, 117
Talismania bifurcata 76
Taractes asper 488
Taranetzella lycoderma 498
Tarletonbeania 147, 158-159
Tarletonbeania crenularis 146, 156, 158, 159
Tarletonbeania taylori 146, 158
Taurocottus 361
Temnocora candida 475
 Tetragonuridae 19, 483, 560-561
Tetragonurus cuvieri 558, 560, 561
 Tetraodontiformes 18, 627-629
Thalassenchelys coheni 3, 32-34, 35

Thaleichthys pacificus 79
Thecopterus 361
Theragra chalcogramma 1, 3, 189-190, 194, 196, 198, 199
Thyriscus 361
Trachinoidei 18, 532-533
Trachipteridae 19, 243, 246-247
Trachipterus altivelis 3, 244, 246, 247
Trachurus symmetricus 486, 487
Trichiuridae 19, 483, 551-552, 553
Trichodon trichodon 532, 533
Trichodontidae 19, 483, 532-533
Triglops 361-362, 412, 413
Triglops A 412, 413
Triglops B 412, 413
Triglops forficata 412
Triglops jordani 412
Triglops macellus 412
Triglops metopias 412
Triglops pingeli 412
Triglops scepticus 412, 413
Venefica sp. 33, 36
Xeneretmus latifrons 456, 460, 462, 463
Xeneretmus leiops 456
Xeneretmus triacanthus 456
Xenocongridae 19, 31-34, 35
Xenomystax atrarius 33, 36
Xeropes fucorum 522
Xiphister atropurpureus 4, 505, 507, 516, 517, 518
Xiphister mucosus 507, 516, 518, 519
Xiphisterinae 504-505, 507
Xiphisterini 504, 505, 507
Zaniolepis frenata 341, 344-345
Zaniolepis latipinnis 341, 344-345
Zaniolepis spp. 341-342, 344, 345
Zaprora silenus 20, 24, 530, 531
Zaproridae 19, 483, 530-531
Zeiformes 18, 257-259
Zesticelus 361
Zoarcidae 19, 483, 498, 499
Zoarcoidei 18, 496-531

Index to common names

- Anchovies 43, 48-49
- Anchovy, northern 48, 49
- Argentine
 - bluethroat 54, 55
 - Pacific 52, 53
- Argentines 52-55
- Armorheads 494, 495
- Arrowtail 184, 185
- Arrowtails 184-185
- Barracudina
 - duckbill 138, 139
 - ribbon 136, 137
 - slender 134, 135
- Barracudinas 134-139
- Barreleye 74, 75
- Bigscale, highsnout 254, 255
- Bigscales 252, 253, 254-255
- Blackdragon, Pacific 120, 121
- Blackdragons 120-123
- Blacksmelt
 - Pacific 62, 63
 - popeye 60, 61
 - robust 58, 59
 - snubnose 64, 65
- Blenny, ocellated 508, 509
- Bocaccio 322, 323
- Bottlelights 104, 105
- Bristlemouths 87-88, 89, 90, 91
- Brotula, red 218, 219
- Brotulas 218-219
- Butterfishes 562-563
- Cabezon 382, 383
- Capelin 80, 81
- Clingfish
 - kelp 232, 233
 - northern 230, 231
- Clingfishes 229-233
- Cockscomb, high 512, 513
- Cod
 - Arctic 190, 191
 - Pacific 194, 195
 - saffron 192, 193
- Codfishes 189-199
- Codlings 182, 183
- Combfishes 344, 345
- Croaker, white 492, 493
- Croakers 492-493
- Cusk-eel, spotted 214, 215
- Cusk-eels 212, 213, 214-215
- Cutlassfishes 551-552, 553
- Daggertooth 140, 141
- Daggertooshs 140-141
- Deepsea smelts 51, 56-69
- Dragonfish
 - highfin 110, 111
 - longfin 116, 117
 - pitgum 114, 115
- Dragonfishes, scaleless 110-112, 113, 114-117
- Dreamer, smoothhead 224, 225
- Dreamers 222-227
- Eelpouts 498, 499
- Eels 31-34, 35, 36, 37, 38-41
- Fangtooth 250, 251
- Fangtooshs 250-251
- Flashlightfish
 - California 150, 151
 - chubby 148, 149
 - northern 152, 153
- Flounder
 - Arctic 604, 605
 - arrowtooth 578, 579
 - Bering 590, 591
 - Kamchatka 576, 577
 - long 584, 585
 - spiny 574, 575
 - starry 612, 613
- Flounders
 - lefteye 568-571
 - righteye 573-623
- Glowingfish 144-145
- Gobies 543-549
- Goby
 - arrow 544, 545
 - bay 548, 549
 - blackeye 546, 547
- Greenling
 - kelp 352, 353
 - masked 356, 357
 - painted 342, 343
 - rock 354, 355
 - whitespotted 358, 359
- Greenlings 341-350, 351, 352-359
- Grenadier
 - ghostly 206, 207
 - Pacific 202, 203
 - threadfin 204, 205
- Grenadiers 200-209
- Gunnels 522, 523
- Hake, Pacific 186, 187
- Hakes 186-187
- Halibut
 - Greenland 622, 623
 - Pacific 592, 593
- Hatchetfish
 - lowcrest 100, 101
 - slender 94, 95
 - spurred 96, 97
 - tropical 98, 99

Hatchetfishes 92-105
 Headlightfish, California 176, 177
 Herring, Pacific 44, 45
 Herrings 43-47
 Irish lord
 banded 372, 373
 brown 378, 379
 longfin 380, 381
 red 374, 375
 yellow 376, 377
 Irish lords 368, 369, 370, 371, 372-381
 Jacks 484-487
 Jacksmelt 240, 241
 Kelpfish, giant 536, 537
 Kelpfishes 535-537
 King-of-the-salmon 246, 247
 Lampfish
 broadfin 168, 169
 dogtooth 160, 161
 giant 170, 171
 patchwork 178, 179
 pinpoint 166, 167
 sunbeam 162, 163
 Lancetfish, longnose 142, 143
 Lancetfishes 142-143
 Lanternfish
 blue 158, 159
 California 154, 155
 northern 172, 173
 Lanternfishes 146-179
 Lingcod 346, 347
 Lizardfish
 California 132, 133
 highfin 130, 131
 Lizardfishes 132-133
 Lizardfishes, deepsea 130-131
 Loosejaw, shiny 118, 119
 Loosejaws 118-119
 Louvar 556, 557
 Louvars 556-557
 Lumpsucker
 Pacific spiny 468, 469
 smooth 466, 467
 Lumpsuckers 465-469
 Mackerel
 Atka 348, 349
 chub 554, 555
 jack 486, 487
 Mackerels 554-555
 Medusafish 558, 559
 Medusafishes 558-559
 Molas 628-629
 Opah 244, 245
 Opahs 244-245
 Oreos 258, 259
 Paperbone, scaly 128, 129
 Paperbones 128-129
 Pearleyes 126, 127
 Pilotfish 484, 485
 Pipefishes 264, 265
 Plaice, Alaska 614, 615
 Poacher
 blacktip 462, 463
 kelp 458, 459
 Poachers 456, 457, 458-463
 Pollock, walleye 198, 199
 Pomfret, Pacific 488, 489
 Pomfrets 488-489
 Pompano, Pacific 562, 563
 Prickleback
 black 516, 517
 bluebarred 510, 511
 ribbon 514, 515
 rock 518, 519
 Pricklebacks 500, 501, 502, 503, 504, 505, 507-519
 Prowfish 530, 531
 Prowfishes 530-531
 Quillfish 528, 529
 Quillfishes 528-529
 Ragfish 538, 539
 Ragfishes 538-539
 Ribbonfishes 246-247
 Rockfish
 aurora 292, 293
 bank 330, 331
 black 314, 315
 blackgill 316, 317
 blue 320, 321
 brown 290, 291
 canary 324, 325
 copper 296, 297
 darkblotched 298, 299
 greenstriped 302, 303
 Puget Sound 304, 305
 redbanded 294, 295
 redstripe 326, 327
 rosethorn 310, 311
 rougeye 288, 289
 sharpchin 334, 335
 shortbelly 312, 313
 splitnose 300, 301
 stripetail 332, 333
 vermilion 318, 319
 widow 306, 307
 yellowmouth 328, 329
 yellowtail 308, 309
 Rockfishes 268-272, 273-280, 281, 282-287, 288-335
 Rockhead 460, 461
 Ronquils 496, 497
 Sablefish 338, 339
 Sablefishes 338-339
 Sanddab
 Pacific 568, 569
 speckled 570, 571

Sanddabs 568-571
 Sandfish, Pacific 532, 533
 Sandfishes 532-533
 Sandlance, Pacific 540, 541
 Sandlances 540-541
 Sardine, Pacific 46, 47
 Sauries 236-237
 Saury, Pacific 236, 237
 Sculpin
 Arctic staghorn 394, 395
 bald 428, 429
 buffalo 390, 391
 calico 424, 425
 crested 448, 449
 darkfin 442, 443
 darter 408, 409
 fluffy 432, 433
 grunt 366, 367
 manacled 410, 411
 mosshead 426, 427
 Pacific staghorn 446, 447
 padded 414, 415
 prickly 444, 445
 Puget Sound 384, 385
 rosylip 386, 387
 roughback 388, 389
 sailfin 454, 455
 scalyhead 416, 417
 sharpnose 422, 423
 shorthorn 402, 403
 silverspotted 450, 451
 slim 406, 407
 smoothhead 418, 419
 soft 434, 435
 spinyhead 440, 441
 tadpole 436, 437
 thornback 404, 405
 tidepool 430, 431
 Sculpins 360-362, 363, 364, 365, 366-455
 Seadevils 222-223
 Sea raven, shaggy 452, 453
 Silversides 238-241
 Skilfish 338
 Slickheads 76
 Smelts 51, 79-81
 Smoothtongue
 California 68, 69
 northern 66, 67
 Snailfish
 longnose 480, 481
 prickly 478, 479
 tadpole 476, 477
 Snailfishes 465, 460, 471-473, 474-481
 Snipe eel
 blackline 38, 39
 slender 40, 41
 Spiny eels 31-35

Sole
 butter 594, 595
 C-O 616, 617
 curlfin 618, 619
 deepsea 580, 581
 Dover 608, 609
 English 610, 611
 flathead 588, 589
 petrale 582, 583
 rex 586, 587
 rock 596, 597
 sand 620, 621
 slender 606, 607
 yellowfin 602, 603
 Spookfish
 javelin 70, 71
 winged 72-73
 Spookfishes 70-72, 73, 74-75
 Squaretail, smalleye 560, 561
 Squaretails 560-561
 Sunfish, ocean 628, 629
 Thornyheads 336, 337
 Tomcod, Pacific 196, 197
 Tonguefish, California 624, 625
 Tonguefishes 624-625
 Topsmelt 238, 239
 Tubeshoulders 77
 Tube-snout 262, 263
 Tubesnouts 262-263
 Veilfin, bigmouth 490
 Veilfins 490, 491
 Viperfish, Pacific 108, 109
 Viperfishes 108-109
 Whalefishes 256
 Wolf-eel 526, 527
 Wolffish, Bering 524, 525
 Wolffishes 524-527
 Wrymouths 521, 522
